Entered, according to Act of Congress, in the year one thousand eight hundred and sixty-five, by

HARPER & BROTHERS,

in the Clerk's Office of the District Court of the Southern District of New York.

THIS WORK

Is respectfully Dedicated

TO THE

MEDICAL PROFESSION OF THE UNITED STATES,

BY THEIR OBEDIENT, HUMBLE SERVANT,

THE AUTHOR.

PREFACE TO THE FIRST EDITION.

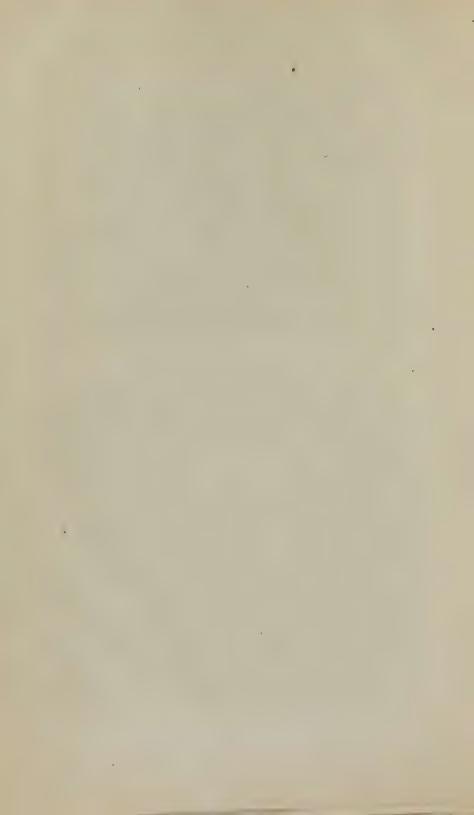

'THE Author of this work has endeavoured to keep before him the difficult objects of adapting it to the student in medicine and to the more advanced. For the advantage of the former, therefore, he has aimed at such method as he might command, and such illustration as might not seem irksome to the latter. With a view to the former, also, he has endeavoured to indicate the intimate manner in which all the topics embraced in the work are related to each other, and their mutual dependences, by constant references from one part to others: and, what is unusual, the Author has made these connecting references in a prospective as well as retrospective manner. With a view, also, to the same objects, the Author had designed a more copious Index; but as the stereotype was completed as long ago as the middle of November, and as the state of his health, and other avocations. have not permitted him to complete the Index, in its regular order, beyond the 125th page, he has concluded to print it as it now stands, and to extend it in a future edition. Many subjects, however, throughout the work, are now incidentally carried out in the Index; but many of the most important receive only a general reference, excepting as they are related to others which are more amply noticed.

New York, Jan. 1, 1847.

PREFACE TO THE FOURTH EDITION.

THREE Editions of these Institutes, the first of which was published in 1847, having been exhausted, the Author now submits a fourth to his medical brethren, in which he has endeavoured to incorporate, in an Appendix, the most important of the recent discoveries in Physiology, Pathological Anatomy, Therapeutics, Organic Chemistry, and Microscopy that are relative to the principles about which this work is interested, and he has connected the Appendix intimately with the main body of the work by copious references to the sections embraced in the former, while the same system is carried out reciprocally in the latter. It is also gratifying to the Author to pay his humble tribute of admiration particularly to the immense labors of the microscopist, who, through the great improvements of the instrument, is now enabled to analyze with surprising accuracy the ultimate and varying conditions of the solids and fluids. The Author has also fulfilled his design, as expressed in the Preface to the first edition, of extending the original Index, a second one being now added, in which he has endeavoured to present an epitome of the whole work. It is proper, however, to suggest that the Reader will find an advantage in consulting simultaneously the original Index, as it is more particularly analytical. An Essay upon the Soul and In-STINCT forms a part of the APPENDIX.

NEW YORK, November, 1857.

PREFACE TO THE FIFTH EDITION.

THE preceding Edition of 1857 having become exhausted, the Author presents another, in which some remaining typographical errors are corrected, numerous references to sections introduced, and a Sur-PLEMENT added. Another Preface enables him, also, to express his sense of obligation for the generous opinions which have recently appeared in the Medical Press of his various professional writings. It is especially gratifying that this tribute has been rendered with great unanimity in his own country, and he desires no greater reward for his toil and anxiety. But he by no means intends to imply that his doctrines have been always accepted, although they have been very generally allowed to be logically sustained. And the Author feels it his right to say that, in all the critical reviews which have fallen under his observation, whose object has been to affect his writings injuriously, such reviews have consisted altogether of falsifications and perversions of his statements and opinions. Nor is this unqualified assertion made without a full knowledge that all the objections alleged have been critically examined, and the results placed upon record, and from a belief, also, that it is due to the interests of medicine. Some of the false and ungenerous reviews the Author thought it worth while, many years ago, to expose in elaborate articles. But his particular motive for referring now to the subject is to express his thankful acknowledgments to his friend Professor Charles A. Lee, M.D., and to Professor James B. M'Caw, M.D., the distinguished Editor of the Virginia Medical Journal, for having, with great ability and disinterestedness, performed a similar labor in his behalf. But he would not, therefore, have it inferred that he supposes his writings are invulnerable, and he would much honor the critic who would employ himself fairly in refuting any doctrines or opinions that may be open to objection.—See Note W p. 1127.

The Supplement which is added to the present edition embraces observations that go to corroborate some of the Author's principal views in medical philosophy; but he is not aware of any discoveries in Physiology, or of any new facts in Pathology, or of any improvements in Therapeutics since the late edition to affect adversely any of his doctrines. Indeed, as a work of principles, and as a consistent whole, should any doctrine of importance be shown to be fallacious, the entire fabric must be abandoned. But if, on the contrary, its principles be founded in Nature, they can not be affected by any future accumulation of facts—no more than the law of gravitation was

rendered more absolute by the successful calculation of the periodic time of Halley's comet. That achievement was simply a corroboration of a great discovery. It is of no importance, therefore, to the essential objects of this work to introduce new discoveries till some one or more may present themselves, that, like chlorine, iodine, &c., in their relation to Lavoisier's theories of oxygen, shall invalidate the system of medical philosophy herein embraced; by which the Author means such facts as can be undeniably shown to contradict that philosophy. This, it is true, will appear strange to those (and of such there are many) who look upon principles as "liable to exceptions" —as having no stability—exposed to daily fluctuations—as consisting even of isolated facts; such philosophers, particularly, as see no discrepancy between the conflicting laws of organic and inorganic beings, and who, therefore, are ever ready to engraft them indiscriminately upon organic philosophy, or as one or the other may have its chance in the irresistible pronunciations of organic life, or in the spurious analogies of simple matter. To multiply facts in this work which merely contribute to the validity of its principles, or to incorporate others that may be speciously arrayed against those principles, would constitute a defect for the most ordinary criticism. Nevertheless, some things, both of the former and latter nature, have been admitted into the Appendix, although precisely parallel facts occur in the body of the work. But they were said to be new, and the Author yielded to this general belief, though he concedes that the facts are more fully displayed in the latter than in the former cases, and that he therefore contemplated an advantage from their corroborating effect. But their exclusion would not have otherwise affected the work, though it might have been regarded by some as a defect. The same may be also affirmed of the Supplement, where, for example, some late observations relative to absorption by the intestinal villi are stated, although they simply confirm what had been long ago ascertained; but they are more precise and complete, and place the doctrine in these Institutes beyond question. Again: Richardson's late experiments tending to show that the blood's fluidity is owing to ammonia were not admitted into the Appendix, as the Author believed that they were contradicted by the general philosophy of life; but reference is made to them in the Supplement because they have been contradicted by other and later observations. would be superfluous to add that it would have been irrelevant to the objects of the work to have gone into the minutize of histology, to have even introduced the discovery of white globules in the blood, or the late observations upon the supposed tributary influences of the spleen and thymus upon the blood, &c., since they have no bearing upon a work of general principles (§ 83 c).

NEW YORK, August, 1859.

PREFACE TO THE SIXTH EDITION.

A CAREFUL attention has been bestowed upon this sixth edition, as will be sufficiently manifest in the numerous references which have been added to the sections wherever the subjects under consideration are allied to other parts of the work and may derive illustration through this relationship. These new references (which occupy mostly the former vacant spaces at the end of sentences) are prospective as well as retrospective, and amount to more than seventeen hundred; and the Indexes have been improved in a similar manner. The Author has also endeavored to simplify the exposition of some of the most difficult problems, and to thus render them of more easy comprehension by the young medical student. For this purpose he could have equally desired greater amplification, and especially to protect himself against misapprehension or misrepresentation (from the latter of which, however, he is not so unwise as to hope for escape); but the vastness of the field, the immensity of the labyrinth which he has explored, has rendered it necessary to employ as much brevity as such variety and intricacies would admit, and he has considered it most expedient to carry into the APPENDIX and Supplement the same compactness that characterizes the body of the work. Of the Supplement it is said that "it is very brief, but speaks a volume."

But whatever advantages in respect to detail and perspicuity may attend a work upon the principles of medicine as founded in Nature, it can have but little chance with other systems unless the student be ambitious of knowledge, and disposed to grapple at the very beginning of his career with the difficulties of truth as distinguished from the fascinating simplicity of error. The latter once impressed upon his imagination, or once productive of mental indolence, fetters his aspirations and decides his destiny. Hence the incalculable importance of a right beginning. Whatever the apparent obstacles, they may be soon surmounted. The task will have been the best possible mental discipline for the young inquirer. He will have learned the important art of thinking for himself; and when once inducted into the true philosophy of medicine he can not help thinking, and into the very depths of that philosophy. He will have also shielded himself against the seductions of artificial systems. He will quickly distinguish what is true in Nature from factitious analogies. He is not, however, to be discouraged from informing himself of spurious doctrines; and with this object in view the Author of these Institutes has incorporated in the work a copious exposition of the offsprings of

error. But, as he has also endeavored to indicate their fallacies, the student has the double advantage of learning the inventions of art and at the same time the infirmities which are so apt to commend them to our natural indolence. The Author's method, therefore, if he be right in his premises, is not open to the objection alleged by Burke (but on the contrary defeats it), that—"When education takes in error as a part of its system there is no doubt that it will operate with abundant energy and to an extent indefinite."

Much has been recently said by a few writers upon the recuperative law of Nature, and presented in such a manner as to convey an impression that now, for the first time, the old doctrine of the vis medicatrix natura has been distinctly announced. The Orator, for example, of the London Hunterian Society for the present year remarks that—"From time immemorial the professors of the healing art, with one or two exceptions, seem to have known nothing of the course and termination of diseases, save in connection with, and as modified by, special therapeutical agents. Nearly all their reasoning upon the action of medicines has, in consequence, been based upon comparisons of one method of treatment with another. They seem never to have thought of taking as the basis of their reasoning the curative resources of Nature herself, as ascertained by study of the natural course of disease."

It is evident that they who have lately written in the foregoing manner have had their attention diverted from Hippocrates, Celsus, Galen, &c., and if they will turn to the mottoes at page 661 of this work they will find that those early masters "took as the basis of their reasoning" what is supposed to be of such very recent origin. And the Author of these Institutes, unwilling to be excluded, may be permitted to assure these reformers that throughout the work he has "taken as the basis of his reasoning the curative resources of Nature herself, as ascertained by study of the natural course of disease." It is the absolute foundation of all his Therapeutics, and the foregoing mottoes were employed to indicate the fact. But these reformers have, also, nearly as large a reliance upon Nature as the homeopath, with much less regard for the noble science, and appear to be of Magendie's opinion that "the nurse can prescribe equally well" (§ 744); and perhaps this may be what is intended by claiming for the honor of the present age the discovery of the vis medicatrix natura. In that aspect of the subject the Author of these Institutes does not sympathize (excepting as it respects a few "selflimited" diseases, and multitudinous cases in which there is no profound derangement, results of mechanical injuries, &c.), although he endeavors to expose the errors of excessive medication, and agrees with the abortive disciples of Nature that wherever this practice obtains (as it does with the mass of the profession) the whole work of cure is supposed to devolve upon art; and this, he maintains, is the inevitable effect of the chemical and humoral doctrines.

Such is a glance at some of the objects of this work, and to which the Author invites especially the impartial attention of the young student of medicine, and with the assurance that he will meet with no timid or unfair concealment of doctrines that are opposed to those of the Institutes.

There remains to be noticed what may seem to be an isolated subject, but which is essentially relative to physiology—the essay upon the Soul and Instinctive Principle (incorporated in the Appendix), in which the Author endeavors to demonstrate the substantive existence and self-acting nature of the Soul and Instinct upon strictly physiological principles. If this have been accomplished by the Author, who believes the demonstration to be conclusive, then is there an end to materialism; and even he who doubts not the probabilities of the metaphysical inductions, or relies with greater confidence upon Revelation, must realize a new satisfaction in that tangible proof which no ingenuity can invalidate, no misrepresentation pervert, and no sophistry evade.

As to the Author's reference to his essay upon "Theoretical Geology" (p. 908, 927), it will be seen that the work embraces many facts that are allied to organic philosophy; but it is now his object to state that the discussion proceeds upon recognized grounds in natural philosophy, chemistry, geology, &c., and without departing from the rules prescribed by "positive science;" and as the Author's aim is simply the development of truth, he entertains the hope that the essay may be scrutinized according to its supposed philosophical premises. The issue must ultimately turn upon this mode of investigation, not upon the usual ground of geological hypotheses, which, indeed, are the very things in question. It must be decided in the open field of those various sciences which constitute the physiology of Nature; since the near affinities among the facts in geology constantly bring them under the collective interpretation of the different departments of knowledge, and no one who has not directed his attention to the whole circle of the sciences is qualified to grapple with the subject.

NEW YORK, September, 1860.

PREFACE TO THE EIGHTH EDITION.

A SEVENTH edition of this work was published in 1861, which, as stated in a Preface, "is distinguished from the preceding editions by the addition of several brief foot-notes and some other improvements." In 1862 appeared another edition, but under the designation of the seventh edition, though distinguished from that by the addition of twenty pages of Notes appended at the end of the Second Index, and by frequent references to them in the text, and also by the addition of several brief foot-notes, and by many references to sections throughout the work. Doubtless it had been better to have entitled that edition the eighth.

The present edition is distinguished from the last particularly by an extension of the Nores at the end of the Second Index, and by numerous references to them in the text. Several of the former Prefaces are reproduced as memoranda of the progressive condition of the work. In the Preface to the seventh edition, which is now omitted, there occurs the following explanatory statement: "The author embraces this opportunity to say (what may not be obvious to all) that the fractions which appear in many of the numerical designations of the sections, as $\S 303\frac{1}{4} \alpha$, are intended for sections that were made after the original completion of the manuscript, by which the labor of a revision of the entire work was saved. The addition of letters to a series of figures of the same denomination indicates distinct sections, but that they are either closely allied, or are intended as substitutes for fractional parts."

The foregoing Preface, with the edition to which it refers, appeared in the year 1865. In 1867 there was printed an "Eighth Edition Revised," and the present is a reprint of that Edition, in which improvements had been made.

New York, 1868.

INSTITUTES OF MEDICINE.

PRELIMINARY REMARKS.

"Until it is proved that the forces which, in a living body, interrupt the play of the natural chemical affinities, maintain a proper temperature, and preside over the various actions of organic and animal life, are analogous to those admitted by natural philosophy, we shall act consistently with the principles of that science, by giving distinct names to THESE TWO KINDS OF FORCES, and employing ourselves in Calculating the different Laws they ouer."—Andral's Pathological Anatomy. See, also, Medical and Physiological Commentaries, vol. 1, p. 626-632.

"Our notion of life involves something more than mere reproduction, namely, the idea of an ACTIVE POWER, exercised by virtue of a definite form, and production and generation in a definite form. The production of organs, the co-operation of a system of organs, and their power not only to produce their component parts from the food presented to them, but to generate themselves in their original form and with their properties, are characters belonging exclusively to organic life, and constitute a form of reproduction into DEPENDENT OF CHEMICAL POWERS. This VITAL PRINCIPLE is only known to us through the peculiar form of its instruments; that is, through the organs in which it resides. Its LAWS must be investigated just as we investigate THOSE OF THE OTHER POWERS WHICH EFFFECT MOTION AND CHANGES IN MATTER."—LIEBIG'S Organic Chemistry applied to Physiology, p. 355.

"Simple views, whether of health or disease, however ingenious, can seldom be just. They have their origin in the spirit of system, not in the careful study and faithful enumeration of the complicated circumstances which concur in the production of all vital phenomena."—THOMPSON, on Inflammation.

1, a. Solidism and vitalism will form the basis of these Institutes. If consistent in all their parts, without a violation of facts, it is, prima facie, a proof of their foundation in Nature. To show this consistency, and to develop the great principles and laws of organic beings, and erect a substantial fabric of Institutes which shall guide the hand of art, we must ascend, progressively, along the fundamental facts in physiology, pathology, and therapeutics; till, at last, we proceed to convert the great system to practical uses, in the preservation of health, and a just, intelligible, and philosophical application of the

materia medica to morbid states of the body.

To render this work, therefore, most practical, and to simplify as far as possible the highest department of knowledge, I shall adopt an analytical method. I have also endeavored to arrange the various topics in their most natural order, or as each successive one may appear to emanate from, or to depend upon, the preceding. The student, therefore, to understand the last, must comprehend all the preceding, and so of each in succession. We have thus a connected link throughout; a difficult achievement, and the more difficult as it is the first effort that has been made to present the natural relations of my whole subject in their just order, to point out the affinities, and to exhibit throughout the important laws and essential foundations of vitalism and solidism, and to maintain throughout a consistency of facts and of laws that shall stamp the whole as the *Philosophy of Medicine*.

In making this claim for the Institutes, I am prepared, as in the case of the Commentaries, to invite the most rigid scrutiny.* If there be any where a collision in principles or facts, or any contradictions of myself, let them be pointed out. My aim is truth, and I desire

nothing for myself which I do not yield to others. If there be minor imperfections I would gladly know them. Many of the original doctrines which appear in this work are presented in various connections in the Medical and Physiological Commentaries. The spirit of the Commentaries will pervade the Institutes, as being, in my judgment, the only stable foundation.*

1, b. In the farther prosecution of this work it will still be my object to speak of such errors as have usurped the rights or blighted the interests of rational medicine. It is not now the time for a simple expression of facts, of experience, and of philosophical doctrines. The errors which surround them must be also exposed and refuted, or the foe of truth, or the ambitious aspirant, or the lover of indolence, will gain something from an indulgence which they know how to seek and appropriate. Nor is any one more aware of the tendencies of free discussion or unsparing of physiologists than he who has been most successful in the propagation of error, or who would sooner stifle inquiry into factitious systems. Thus, it is said by Liebig, that

"It is too frequently forgotten by physiologists that their duty really is, not to refute the experiments of others, nor to show that they are erroneous, but to discover truth, and that alone."—Liebic's Organic

Chemistry applied to Physiology, &c.

Now this obvious sophistry betrays its motive, since it is utterly at variance with the habits of him who would enjoin the fiction upon others. Truth should be, indeed, the ultimate object of pursuit; but the first and most important step toward its attainment is the removal of obstacles that may lie in its way (§ 820). It is allowed, indeed, by one of Liebig's most zealous advocates, the editor of the London Lancet, that "the removal of error claims a place next to the establishment of truth" (Dec., 1844); and it has grown into a proverb, that "it is more difficult to subdue a prejudice than to build a pyramid."

Although, therefore, the contemplated method must be sometimes argumentative and controversial, it has the advantage of leading more immediately to a knowledge of the truth upon disputed questions, than any other which is not demonstrative. There can be no doubt, indeed, that the "establishment of truth" in medical philosophy can be effected only by a simultaneous refutation of the errors which surround it. The mind will not surrender a favorite doctrine, however false, to the force of truth alone. Even its practical disasters, as we every where witness, are an inadequate demonstration. But, when error and truth are presented in forcible contrast, it is the pride of reason to embrace the latter. What is also important, the reader will have been presented, as in the Commentaries, with the great rival doctrines in medicine, and in their proper relations to each other (§ 35014).

2, a. The Institutes of Medicine are natural inductions of principles and laws from the healthy and morbid phenomena of living beings. They relate to Physiology, Pathology, and Therapeutics, and to nothing else. All other systems, therefore, must be spurious. The substitutes have no depth, no principle, no laws, and are recommended alone by their naked simplicity. "Gentlemen," says Bacon, "nature is a labyrinth, in which the very haste with which you move will make

you lose your way."

2, b. The immediate objects of physiology are a critical analysis of * The author has seen no reason to modify this statement, made twenty years ago —1867.

the vital conditions and results of organic beings, as manifested in different organs, and in their relations to each other. It contemplates organic nature, therefore, in its natural state; and the laws which it obeys are its highest end. Pathology is to the physician the great final object of physiology. It investigates the causes which disturb the physiological conditions, and inquires into the phenomena, and the nature of the vital and structural changes. These, in connection, form the ground-work of Therapeutics, which considers the indications to be fulfilled, and the means and the manner by which they are to be accomplished, and nature thus aided in the process of cure. The Materia Medica comes last, and is the subordinate object of all the rest. It investigates the composition and physical character of the material objects by which the therapeutical intentions are fulfilled, and interrogates especially their relations, as vital and alterative agents, to pathological conditions. Disease, being a modification of the physiological or natural condition, produces new relations between the properties of life and the natural, morbific, and remedial agents; and these are ascertained by observation of their effects upon morbid states alone. It is thus that remedies become beneficial when they would be morbific in health; and what is salubrious in health is rendered morbific by diseased conditions. The principle is in beautiful harmony with the instability of the vital properties; and the final cause of this instability is the preservation of organic being (§ 133, c, 153-156, 638).

2, c. Nevertheless, each of the four great departments of medicine possesses so many peculiar characters that they may be severally considered as constituting, to a large extent, distinct parts of one great symmetrical whole (§ 83, c). Pathological conditions could never have been inferred, à priori, from any extent of physiological inquiries, nor could the effects of therapeutical agents, or the natural termination of disease in health or in death, from any knowledge of anatomy, physiology, or pathology. The whole is originally the work of observation; and we come to learn the relations of the four great branches of medicine by comparing the phenomena which are presented under the various conditions of health and disease, and as

these phenomena may be affected by artificial influences.

Anatomy, however, affords no such standard of comparison. And yet it is obvious, as will more distinctly appear hereafter (§ 83-163), that anatomy is the basis of medicine. It is, however, of the system of organic life that I mainly speak. All, at least, that is superficial in animal life, the voluntary muscles, &c., abstracted from their relations to the organic condition, belongs to the domain of surgery, and

is, therefore, of little importance to the physician.

2, d. Notwithstanding, therefore, the foregoing qualifications, it will be seen, in our inquiries into the great fundamental points, that the science of medicine is, throughout, a perfectly connected chain; beginning with the laws which govern the modes in which the elements of matter are combined in organic beings,—advancing to the union of organic compounds into cells and tissues,—to the laws which respect the various processes which are conducted by these tissues, and by the organs into which they are combined,—to those laws as affected by the contingencies of disease,—and, lastly, to the laws which regulate the changes through which the morbid states return to

the natural conditions of life. All are connected together by intimate dependencies, and are determined by the natural or by the varying states of the vital properties in their operation through material parts. The ground-work of the whole is, evidently, perfectly simple; since the laws by which the whole is regulated are established upon the

constitution of the organic properties (§ 169, f, 638).

2, e. To the eye of the philosopher, therefore, Nature, in her organic department, as in every other, appears in an aspect of astonishing simplicity, when he contrasts her forces and laws with the diver sity of their phenomena; nor does he confound the principles and laws which distinguish the different departments of nature. To every other eye the phenomena of life appear confused, and seem referable to no common powers or laws. But he who has obtained the key to the true philosophy of life, by a wide observation of nature, lays open at once the apparent secrets of all its results, whether in health or disease. Whatever he sees has its individuality, and stands in relief from all the rest. He knows at a glance from whence this or that springs, how it is related to others, and he traces the whole directly up to a few simple principles. To all but such an eye, however, the phenomena of life, and more especially of life diseased, appear as does a field to all but the botanist. The common observer sees nothing but a confused assemblage of grasses, and probably will tell you there is but one species where the botanist will as instantly discover fifty. Each species has to the latter a distinct individuality, and he cannot regard them in that state of confusion which is seen by the ignorant. He has studied each plant, knows its specific characters, its relations to others, its habits, &c. By these modes of observation he has also acquired the knowledge that nature has pursued a common plan of organization, and linked the whole, by close analogies, throughout the vegetable kingdom. Were the botanist, therefore, to range simultaneously among the 100,000 species of plants, he would see nothing but individuality, and the greatest simplicity in the principles upon which the whole are constituted. And just so it is with a philosophical observation of the healthy and morbid phenomena of the animal kingdom.

3. The organic and inorganic kingdoms have, respectively, their peculiar properties and laws. Such as appertain to life, in its natural, as well as morbid aspects, are denoted by an incomparably greater variety of phenomena than those of the external world; and as their only intelligible foundation is the phenomena evinced, we attain our knowledge of either according to the extent and variety of

the phenomena. We know nothing more of matter itself.

Without a comprehensive knowledge of the properties and functions of living beings, and especially of the laws by which they are governed in their healthy and morbid states, the practice of medicine is mere empyricism. The ignorant, alone, undervalue causes and

principles, and depend upon unconnected facts.

4, a. In medicine, therefore, we must concern ourselves with something besides effects. We must understand the laws under which they take place, and, as far as possible, trace up the effects to the primary causes. This is always done in other sciences and in the arts. Why, then, should it be neglected in that science whose practical application relates to the highest welfare of man?

The human mind will have its theories upon all subjects; and the whole history of medicine is a perpetual exemplification that in no inquiries do theory and hypothesis abound so universally as in the healing art (§ 819, 960). This arises, in part, from the intricacies of the subject, but mostly so from the constitution of the mind itself. The Almighty designed it for theoretical conclusions, and set us the example in those stupendous theories upon which the universe, and all it contains, are founded. And what else are, or should be, our inquiries and our theories, than finding out and adopting those of which He is the author? What other theory in the natural world can there be than such as are instituted by the Almighty Being? And shall we hesitate to embrace, and to act upon such theories? And yet it is one of the pretended improvements of the day to insist upon nothing but facts, and to denounce all principles in medicine; as if the Almighty had not ordained principles and laws as well as facts, which are mere emanations from the former.

4, b. The ignorant pretender will tell us that all this is unimportant; though no one is so much directed by hypothesis, or theory, as this very pretender himself (§ 884). Does not every empiric in the land prescribe his drastic cathartics for the purpose of cleansing the blood of its supposed impurities? Are they not exactly on a par, in their doctrines, and in their practice, with the most speculative of our enlightened humoralists? Nay, have the ignorant portion of that sect, our Brandreths, our Morrisons, et id omne genus, any reference whatever to facts or experience? Is it not all hypothesis, and, therefore, all a reckless waste of human life? Mount up the scale, and you shall find at every step of your ascent, from him who prowls about the outskirts of the profession, to him who directs the all-potent drug with the most consummate skill, that each and all rely mainly upon their conceptions of the philosophy of disease. But you shall also find, that in proportion as Nature has been taken for their guide, and as medical principles are founded upon the absolute phenomena of life, in their healthy and morbid aspects, there will always be the greatest reference to facts and experience.

Hence, again, the importance of looking well to our theories, and of seeing that they are established on well-grounded facts, or on the analogy to which they conduct us. Could we, as we cannot, direct the treatment of disease without principles, we never should; and it should therefore be the business of the practitioner to enlighten his mind upon the philosophy of medicine, or his unavoidable disposition to theorize may prove a scourge to mankind. Of this, indeed, the records of medicine abound with examples (§ 801, b, 819, &c., 960, 1005, 1068).—Notes F p. 1114, Ee p. 1133, Fr p. 1135, Ge p. 1138.

It will therefore be my agreeable task to expose, in these Institutes, the fallacies of the prevailing physical doctrines of life and disease, as well as to inculcate principles which exalt our science above the mere world of matter, render it consistent in all its details, and present it to the profession as a department of knowledge fundamentally distinct from all other pursuits.—See Rights &c. p. 912.

Differences of opinion on questions of great moment to mankind are apt to be strongly conveyed, and apparent error to be censured in no measured terms. This, perhaps, is often admissible, considering the obstinacy of error, and so long as it is the doctrine and not its au-

thor, which is assailed. We may revere the names of Voltaire, of Hume, and of Gibbon, yield them a proud rank in the scale of intellect, and gratefully acknowledge the rich legacies they have left behind. But, who of us would hesitate to speak of their infidelity according to its nature and tendencies? This is even demanded by what we believe of the precepts of religion. And so of the principles of medicine, which hold as high a relation to the temporal interests of man as do the precepts of religion to his spiritual welfare. The highest order of intellect is often devoted to the dissemination of error, and perhaps more frequently in religion and medicine than in any other of the great interests of mankind. This must be fully and firmly met, not only by evidences of the truth, but by an exposure of its perversions and corruptions.

 $4\frac{1}{2}$, a. The physiological world has been lately divided into three schools. One of these sects virtually regards organic nature as a part only of inorganic, endowed with the same properties and governed by the same laws. It maintains, in short, that there is no essential difference between a man and a stone. At the head of this school stands • Liebig, the distinguished and able chemist. It is a great and powerful school, but is falling, daily, beneath the weight of its vast errors and corruptions. It is denominated the *chemical school* of medicine.

 $4\frac{1}{2}$, b. Contrasted with this is the school of vitalism, which regards organic and inorganic nature as distinct in their most essential attributes. It supposes that each department is governed by properties and laws peculiar to itself. It regards the organic being as fundamentally distinct from the inorganic in its elementary constitution, in the aggregation of its molecules, in the structure of its parts, in its condition as a whole, and in every phenomenon which it evinces. It sees design in every part of the living being-eloquent even in the dry bones of a skeleton; a design peculiar to every part, while all concur together to the common ends of the more universal designs of procuring the means of sustenance, of maintaining life, of perpetuating the species, &c. On the other hand, this school discerns no corresponding design in the constitution, or in the condition of inorganic matter. It sees nothing here but mere vis inertia, which, however, is supposed by the chemical school to be capable of evolving from simple matter every variety of organization, with all its specific designs, even instinct and reason, while, at the same time, we hear from the depth of materialism that "organic nature is the mystery of mysteries"—the Creator being the only "mystery" about it.

Again, the vitalists, in consideration of the facts now stated, maintain, in the language of Liebig, the great head of the school of mere physics, "the existence of a principle distinct from all other powers of nature, namely, a vital principle;" which organizes and governs all living beings, and which is the fundamental cause of all their phenomena in health and disease. I say, in the language of Liebig, "a principle distinct from all other powers of nature;" for this mere chemist, in his conflicts with living nature, concedes the existence of such a principle as at the foundation of all vital phenomena, yet, in the same general manner, and on all specific questions where he had introduced its direct and exclusive agency, he as unequivocally declares that there is no such principle, and that every result of life and disease, even thought itself, are entirely owing to chemical agencies

His whole system, as set forth in his "Organic Chemistry applied to Physiology," and in his "Animal Chemistry" as applied to Pathology and Therapeutics, is a tissue of similar contradictions, and of the boldest assumptions. Yet, with deep mortification I say it, he has been hailed with an enthusiasm before unknown in the annals of medicine, as the only true expounder of physiology and of medical philosophy. The world, however, is fast awaking from its spell-bound delusion, and the doctrines of this "reformer" will soon be mingled with the same and more original chimeras which did their part in

"the dark ages of science" (§ 350, 1029, 1030, 1034).

4½, c. Finally, the third school, or that of chemico-vitalism, endeavors to form, as it were, a bond of union between the schools of pure vitalism, and of pure chemistry; though such an alliance be as unnatural as human brains in a block of granite. The chemico-physiologist makes a compromise with philosophy, and takes for his rule "in medio tutissimus ibis." It is as regardless as the school of pure chemistry of the universal consent with which physiology has been hitherto restricted to the condition, functions, results, and laws of living beings, and chemistry to the condition and laws of dead matter. This school, therefore, mingles the doctrines of vitalism and chemistry; allotting to the former one half of the phenomena of life, and the other half to the latter. This is the school to which the young student has the greatest chance of becoming the victim; for it is apparently recommended by the conciliatory principle which I have stated in the form of its motto, and by many of the most distinguished members

of our profession. $4\frac{1}{2}$, \tilde{d} . I have said that it is a remarkable characteristic of the medi cal school of pure chemistry, that its doctrines are in perfect conflict with each other, as shown in a work (Liebig's "Animal Chemistry") which is assumed as the basis of the chemical philosophy of life—as the great foundation on which the school itself has been erected. And how could it be otherwise, seeing that this school, and this writer, are constantly employed about two subjects which have no affinities; that is to say, the philosophy of life and the philosophy of chemistry? I shall think it of sufficient importance to substantiate the foregoing fact by many proofs in the course of this work; and, as an example of the whole, I shall adduce the contradictory views which are put forth upon the most important principles which lie at the foundation of organic life, and at the basis of medical science. On the very subject of a vital principle itself the genius of the school is as flatly contradictory as on the most unimportant doctrine; for at one moment he avows the existence of such a principle "distinct from all other powers of nature," and calls it "the vital principle," which, he says, governs all the processes of living beings (§ 59, 60), and at the next moment he asserts that, "in the animal body we recognize, as the ultimate CAUSE OF ALL FORCE, only ONE CAUSE, the chemical action which the elements of the food and the oxygen of the air mutually exercise on The only known ultimate cause of vital force, either in animals or in plants, is a chemical process."

He renders, as will be seen by ensuing quotations (§ 350), what he assumes as an original fundamental cause of life the indispensable source of another cause, which he avows to be equally original and fundamental; and what is yet more indicative of the chaotic state of

the chemical speculations relative to living beings, this author (as I have shown in the Medical and Physiological Commentaries of many others) assumes, at one time, the chemical force to be the sole cause of all vital processes and results, while, at another time, he regards the vital principle as the only power concerned in the same phenomena. It will be gratifying to curiosity, for example, to observe how Liebig entangles his reader, as it respects the physiology of digestion, by making that process to depend on a purely chemical action, and to evolve that vital principle which he as unequivocally declares to be the only power concerned in chymification (§ 350, nos. 3, 17, 51, 58).

5. Chemical and mechanical philosophy, as we have already seen, are strangers to the philosophy of medicine. There is a natural conflict between the subjects of each. They have no relationship, no sympathies, but carry on a perpetual hostility. The organic being is forever converting to its own uses the inorganic, and changing its very nature into its own. The inorganic is fruitless in resistance and in assault, till the former is passive. It then lays waste the fabric by which it had been wrought into a great system of designs, and degrades the whole to its own level. Chemistry, therefore, begins where physiology ends; and physiology begins with organic influences upon the elements of matter, or where chemistry leaves off. No department of medicine has any thing to hope from chemistry beyond its power of analysis (§ 1029, 1030).

And yet do the labors of chemists aspire at a substitution of the ever-fluctuating principles of chemical science for all that has been hitherto founded upon the phenomena of life and disease. Their oft repeated effort to carry a science which is mainly analytical and mechanical into that which is eminently intellectual and overflowing with the most sublime institutions, and distinguished by the most profound principles and laws of nature, and therefore seductive to an ambition which is restif under the practical manipulations of the laboratory, would raise no inquiry as to motive, or end, did not the proper guardians of the science not only abandon their old and rich domain at the very approach of the enemy, but, with most unnatural distrust

of self, invite the destroyer (§ 349, d, 433, p. 719, § 960, a).

The late publication of Liebig's "Animal Chemistry" has abundantly proved the truth of what I sufficiently established in the "Medical and Physiological Commentaries," that the recent application of chemistry to physiology and medicine is not a partial, but a complete substitution of that science. In justification of all this, we are now told that the means of investigation, of analysis, and of creation, have received an extension of which our predecessors had no knowledge. Such, however, has always been the pretext of chemistry for its invasions upon the science of life. Take, for example, the words of Fourcroy, who wrote more than sixty years ago, and who, like Liebig and his school, attempted to substitute chemistry for physiology, and to rear up a fabric of medicine upon that imaginary foundation; and this, too, in the case of either of the masters, without having ever read a medical book, or having ever prescribed for a disease. language of Fourcroy is exactly such as we now hear from the lips of Liebig and his followers; who cheerfully allow that nothing flowed from the labors of Fourcroy to illuminate the dark ways of organic life (§ 1029, 1030).

So identical are the language, and ambition, and hope or confidence, and the visionary speculations, of the older and recent chemists, that a space may be well assigned to this exposure of chemical pretensions. We read, then, in Fourcroy, what we read in the works

of Liebig and his cotemporary chemists. Thus:

"The errors of the chemical physicians of the last century, and the indifference many practitioners of the present time seem to have for chemistry, have produced a disadvantageous opinion in the minds of many persons, which time alone can remove. If the enthusiasm of those physicians, who cultivated chemistry, misled them, it does not follow that any conclusion can be drawn from thence that may be applied to the present time. THE EXACTNESS WHICH THE MODERNS have introduced into every part of experimental philosophy ought to remove the apprehensions of such as, for want of acquaintance with the subject, are apt to imagine that chemistry is still the dark, mysterious science it was a century ago." "It is chemistry alone that can throw any light on the composition of the fluids, and the changes they undergo by the processes that are carried on during life. We cannot avoid having recourse to this science, in our endeavors to discover the true mechanism of the animal functions; the properties of the fluids separated by the different viscera; or the alterations such fluids undergo." "It will be necessary to enlarge and multiply these researches on subjects of different age, size, and temperament, in various climates and seasons, and to pursue them among the different classes of animals," &c. "We think it equally necessary to examine the solids, by chemical methods, as well in the sound as in the diseased state, and by a comparison of their properties, endeavor to discover to which of the fluids they owe their formation; and this being known, we may proceed to conjecture, in morbific dispositions, the solid or fluid that has suffered a change.

"If it be thus established that the theory of medicine is capable of receiving the most essential advantages from chemistry, it is equally certain that the practice is no less in need of the same assistance; since both must of necessity accompany each other, and are promoted by the same means." "Nothing can be more evident than that the choice of aliments, and of air, cannot be made with any certainty, but in consequence of chemical researches into the nature of foods, and the properties of the atmospheric fluid" (§ 18).—Fourcroy's Medical Chemistry, 1782.—Also, Appendix § 1028-1030, 1034, Lehmann.

I have said, in the Commentaries, that "a prosperous harvest" was promised from Fourcroy's reformation. But, again I reiterate, where is the evidence? since which time, also, chemistry has made greater advances than any other science, has had its unmolested sway, and Fourcroy's example has been followed with a corresponding diligence. Can you point to a solitary instance in which organic chemistry, except in a negative sense, has advanced the science of life or disease? Do not the very chemists of this day incidentally allow the perfectly abortive nature of their science in relation to physiology and medicine? Consult the quotations in section 350, b, 1, &c., and 350\frac{1}{4}-350\frac{2}{3}. Or take the affirmations of the distinguished Mülder (\xi\sigma 350\frac{3}{4}), which go, with the rest, to establish the truth of my former assertion, that "chemistry has been a perfect incubus upon medicine; and the time is not distant when it will have proved, by its own showing, its want of

relation to our subject, if it have not done so already."-Comment., vol.

i., p. 586, note.—See Appendix § 1028-1030.

δ₄, a. I agree with the chemical physiologist that "facts are stubborn things," and, with the analogy which reposes upon them, are at the foundation of all philosophy; but it does not equally follow that facts are always philosophically or even honestly applied, nor that he who devotes himself to the laboratory is the best qualified to apply his own facts to organic nature. "We can have no very high idea of experiments made by gentlemen," says Hunter, "who, for want of anatomical knowledge, have not been able to pursue their reasoning even beyond the simple experiment itself." Least of all can the chemist be permitted to charge upon the vitalist a neglect of chemical facts; since it is as well by these as by the phenomena of life that the vitalist overthrows the artificial system (§ 350–350²/₃). Nor let it be forgotten that it is purely by an appeal to certain false analogies, and by a disregard of the phenomena of living beings, that the physical and chemical hypotheses of life and disease have obtained their ascendency (§ 733, d).

All our theories and principles in medicine, it cannot be too often reiterated, should rest upon well-ascertained facts. The great difficulties with which truth has had to contend since the restoration of the proper method of observing nature consists in the mistaken nature of facts, or of false conclusions from admitted facts. What is often assumed to be fact is just otherwise, and, where the premises are sound, they have frequently led to spurious theories (§ 350½-350¾,

433, &c., 493, 823, &c.).

 $5\frac{1}{4}$, b. The phenomena of nature are the facts about which all philosophy is concerned, and therefore form the substantial ground of all intellectual acquirements. As they relate to organic beings, to their laws, their properties, their functions, whether morbid or healthy, they are to be found in the organic being himself, not in the workshops of the chemist or of the mechanical philosopher. But, even where the mind admits this proposition, if prone to speculation, it too often regards each fact by itself, and rears up hypotheses wrong in themselves, and in conflict with each other. Facts should therefore be compared before they are reduced to theory; or, where they may conflict with acknowledged principles they should remain in an isolated state till their true nature may be better understood, or till the principles which they appear to contradict may be shown to be erroneous. Should some fact, for example, appear to indicate the dependence of life upon chemical or any other physical forces, the evidence to the contrary is so various and conclusive, that that fact must be considered as deficient in some of its elements, which, if known, would readily bring it under a well-established principle in physiology. These absent elements are some other facts which escape our observation; and thus what is truly fact, in an abstract sense, is made the ground-work of important error.

5;, c. It is the peculiar misfortune of science to generalize too hastily; and it often happens that the explosion, or the introduction, of one error, is the parent of many others. It is also astonishingly true that a few phenomena are abstracted from the whole, of which they may be only sequences of the others, and are made the ground of conflicting doctrines, and substitutes for the theories that are insti-

tuted upon the more fundamental facts; and thus a blind disregard of consistency is permitted to prevail till a most incongruous series of assumptions, as in Liebig's Animal Chemistry, is presented to us as the science which Nature teaches.

Again, there is a proneness of the human mind to admit of no realities but such as make a strong demonstration upon the senses; and hence it is that the physical and chemical philosophers of life prefer the facts of the laboratory to such as are supplied by organic beings. The former are therefore assumed as the foundation for principles and laws in physiology and medicine; and when it is considered how large a proportion of mankind have not the ability to distinguish the true from the false, especially when the latter is set forth in a confident and dogmatic manner, it ceases to be remarkable that what is comparatively simple, and comes plausibly recommended by the tangible and visible attributes of matter, should command their confidence beyond those realities which can be appreciated only by an exercise of the understanding in connection with the revelations of sense, and which form the ground-work of principles of difficult penetration. There are few, indeed, who are capable of reasoning beyond their senses and the facts themselves, and this is equally true of the chemist, both as to the facts of the laboratory and the phenomena of living beings, whenever he attempts an exposition of the properties and laws of a department of nature which lies not within his sphere of investigation. "Truth, whether in or out of fashion, is the measure of knowledge and the business of the understanding. Whatever is beside that, however authorized by consent or recommended by variety. is nothing but ignorance or something worse" (§ 1034).

5¼, d. It cannot but be conceded, that, as knowledge advances, and the subjects of inquiry become more or less exhausted, ambition is likely to depart from an observation of nature to seek gratification and renown in artificial expedients. This is becoming a prevailing propensity in medicine; and many have left, and are leaving, the bulwark of knowledge to rear up hypotheses upon distortions of nature, which, for their better success, they dignify by the name of "experi-

mental philosophy" (§ 1085).—Note Pp p. 1142.

51, e. In medicine, at least, there is but one kind of experimental observation, which consists in the simple study of the phenomena of nature. Or, if art be applied to give them a fuller development, the means must be such as shall elicit results conformable to the institutions of nature. But aside from chemistry, it has been the fatality of the physiological department of medicine to have been encumbered with rude experiments, giving the wildest distortions to the features of nature. When we consider the wonderful susceptibility of the properties of life, how readily their actions and results are influenced by natural agents, how a drop of hydrocyanic acid, or of the alcoholic extract of nux vomica, applied to the tongue of an animal, will extinguish life in an instant; or that the same may be done by thrusting a needle into the medulla oblongata; or how concentrated miasma may almost as instantly induce an attack of fever; or how a little excess in eating may bring on an attack of apoplexy as immediately fatal as a blow on the region of the stomach—fatal, perhaps, in either case, as the artillery of the clouds; or how simple irritations of a nerve may be followed by death from tetanus; or how all the vegetable and animal poisons, as well as all things else which do not possess natural relations to the properties of life, will variously change those properties and all their results,—when, I say, we consider all these things, we may well imagine the difficulty of imitating nature by the most cautious experiments, or of developing her laws by mutilating the structure of organic beings, or of illustrating those modifications which spring up in disease, by resorting to processes which are foreign to natural influences. Even the greatest experimentalist in modern times, he who has performed more vivisections than any other man, has placed it upon record, that it is one of the most difficult things in physiology to perform an experiment that shall not be liable to objection. Yet no man ever ventured more hastily upon conclusions from such experiments, and none has thrown greater obstacles, in consequence, in the way of physiology and pathology.

 $5\frac{1}{4}$, f. The limits which restrain the interposition of art are very narrow; and when organic nature is brought under the influence of artificial causes with a proper reference to these limits, the resulting phenomena may form a safe ground of reasoning as to the laws by which organic beings are governed. Much has been accomplished, in this way, as to the physiological connections of the nervous system with organic actions, the part which it takes in the morbid processes, the sympathetic communications which it establishes throughout the organization, and the interpretation which it supplies of the operation of remedial agents. Nevertheless, the most important part of our knowledge upon these great and intricate questions is abundantly supplied by the natural phenomena of life, as manifested under the varying conditions of health and disease. And that this is so, is sufficiently evident from the fact, that but little practical information of the foregoing nature has been added, by recent experiments, to what had been known centuries ago. The late experiments, however, upon the nervous system have confirmed what had been deduced from the more natural process of observation, and have developed some useful facts which it might have been impossible to have known by any other method. Such, for example, is the difference of function between the component parts of the spinal nerves; one part being designed for the transmission of sensation and sympathetic influences, the other for the operation of the will and the development of motion. And yet, if analogy were allowed its proper weight in physiological inquiries, as it must be in reality the great basis of medical science,if there had been less pertinacity as to the necessity of abstract facts for every conclusion, we might have come, by a process of analogy founded upon ultimate facts, to a knowledge of the constitution of the compound nerves. This could have been inferred from their complex functions as evinced by their phenomena, and by associating them with the simple elements of cerebral nerves, where it is plainly seen that some of the nerves have, individually, a specific function, and whose phenomena are destitute of complexity.

5½, a. But the reign of "experimental philosophy" which so lately appeared in the mutilations of animals to discover their natural functions; in the injection of corrosive and putrid substances into the circulatory apparatus of animals to illustrate the pathology of human disease; in the transfusion of remedial agents into the same order of beings, and even into plants, to ascertain the virtues of remedies, their

modus operandi as curative agents, and the right treatment of human maladies, has given place to an "experimental philosophy" in which organic life has no participation. This is the "philosophy" against which the observer of nature is now called upon to contend; fraught with far greater evils than the spurious systems which it has so suddenly surprised and superseded. It is impossible to calculate the mischief which must result to mankind from its unrestrained popularity. Something may be gathered from its former effects when chemistry was young; and something from the progress of error under the fresh spur of Liebig's Animal Chemistry (§ 350–350\frac{2}{3}, \$21). We all know how common the enthusiastic belief that this "Reformer" had overthrown all former systems in every department of medicine; and we may take the following editorial passage from the London Lancet as expressing a very common opinion of the profession as to the ap-

plication of chemistry at the bedside of disease:

"As organic chemistry marches on the basis of an improved system of medical practice," says the veteran editor, "it will prove imperative that a rigorous examination of the products of the animal frame, the several humors and excretions of the body, should be employed in the investigation of disease. The period approaches when it will be incumbent on us, not perhaps invariably, but still very often, in prescribing,—say, for typhus, or purpura, or any of the numerous varieties of cutaneous affections, that by a chemical analysis we should first ascertain the constituents and proportions of the proximate elements of the urine, the saliva, the expired breath, the perspired matter, perhaps the blood, the fæces of the patient, before applying our remedies; and this process may have to be gone through not once only, but several times in the progress of the malady." "The time is, we repeat it, approaching when the FOUNDATION OF PRACTICE ON THE LAWS OF ORGANIC CHEMISTRY will form the distinction between the enlightened physician and the mere pretender" (§ 851, 863, e; 883, b).-London Lancet, April 29, 1843. (Also, § 1029, 1030.)

 $5\frac{1}{2}$, b. In the foregoing quotation we have essentially what is now extensively denominated "the progress of medical science," and the nature of the doctrines to which these Institutes are opposed. These Institutes will be found mainly, so far as physics are alleged to be concerned, by the side of all the most illustrious physiologists from Hippocrates to us, whose general views are thus summarily express-

ed by Bichat:

"The organic chemistry of the laboratory," says Bichat, "is the dead anatomy of the fluids, not a physiological chemistry. The physiology of the fluids should be composed of the innumerable variations which they experience according to the different (vital) states of their respective organs." "The instability of the vital powers is the quicksand on which have sunk the calculations of all the physicians of the last hundred years. The habitual variations of the living fluids, dependent on the instability of the powers of life, one would think, should be no less an obstacle to the chemical physicians of the present age."

"Again, had physiology been cultivated by men before physics, I am persuaded that many applications of the former would have been made to the latter. Rivers would have been seen to flow from the tonic action of their banks, crystals to unite from the excitement

which they exercise upon their reciprocal sensibilities, and planets to move because they mutually irritate each other at vast distances. All this would appear unreasonable to us, who think of gravitation only in consideration of these phenomena. And why should we not, in fact, be as ridiculous when we come with this same gravitation, with our chemical affinities and chemical compositions, and with a language established upon their fundamental data, to treat of a science with which they have nothing whatever to do?"—Bichat's Gen-

eral Anatomy and Physiology.

6. We may now readily perceive the reason why chemistry has undergone changes within a few years, while all that relates essentially to the properties and laws of organic beings may have been long since known. The chemist operates, and makes all his discoveries, through the forces and laws of inorganic matter. These he may carry into his laboratory, turn into his test glasses, or involve in his crucible. He can therefore oblige nature to form the same inorganic compounds as she forms spontaneously. He can then separate the elements again, and again oblige nature to recombine them after their original manner. But, can he do the same thing with organic beings? He cannot form the most simple organic compound—cannot even recombine the elements when they are once separated;although he has then the necessary elements, and in their exact proportions. The reason is obvious. The chemist has not at his command in this case, as in the other, the necessary powers; or, as the chemist expresses it, "he cannot place them in the same circumstances as Nature does."

It is clear, therefore, that while the laboratory is the proper place for the study of the inorganic kingdom, we must go to the organic being itself to learn the nature of the powers and laws by which it is governed. These, then, are the reasons why the laws of organic beings have been long so much better understood than those of chemistry. Every thing is artificial in the laboratory, so far as experiments are concerned; and, if these be not the right ones, or be imperfectly conducted, they will either fail to represent nature correctly, or will give her a wrong interpretation. Hence the great instability of this science; and yet we are told that every new theory in chemistry is

applicable to physiology and medicine.

But, it is quite otherwise with organic beings. Here all the experiments are carried on by Nature herself, and they cannot deceive. The various results and phenomena are seen in the being itself, and can be seen nowhere else. They must, therefore, be the true guide. and the only guide, to the powers and laws by which organic beings are governed. These phenomena, too, are astonishingly multiplied in any given being, and new ones are presented as the being may come under new influences. But, this variety is extended almost to infinity when we consider that every distinct species of plants and animals has its peculiar manifestations of life. It is also true that each one of this endless variety is utterly different from any of the phenomena of the inorganic world. And when we take all the phenomena of organic beings in connection, and find a perfect harmony among the whole, the nature of the proof is so various and immense as to conduct us to a right knowledge of the principles and laws of life in all their aspects.

Now all this variety has been perpetually before the observation of mankind, and always presented to our observation by nature herself. It therefore ceases, I say, to be remarkable that the science of life had so greatly outstripped that of chemistry; and it will probably forever remain better understood; since nature is the experimenter in one case, and man in the other.

PHYSIOLOGY.

7. The sensible world is composed of animate and inanimate beings, which, with their difference in composition and structure, has led to their division into the organic and inorganic or mineral kingdoms.

8. The relations between the two great kingdoms of nature, and their contradistinctions, render a general reference to the inorganic indispensable to our physiological and higher branches of inquiry.

9. Animals and plants, which make up the organic kingdom, are essentially dependent on the inorganic; but the latter kingdom is perfectly independent of the organic.

10. The beginning of organization is in plants, which are the pri-

mary source of nourishment to animals.

11. From the foregoing law arises the great fundamental distinction between plants and animals—that the former subsist on the elements of matter, while the latter are nourished by those elements in an organic state. It appears, therefore, that vegetables are more creative than animals (§ 303).

12. All organic substances are compounds of the simple elements of matter. They are combined by the vital powers, while inorganic

compounds are produced by chemical forces.

13. As organization begins in vegetables, it is obvious that a decompounded organic substance can be restored to an organic state only by that vegetable kingdom which was created for the specific purpose of organizing the mineral kingdom, for the ultimate final cause of supplying food to animals. The plant reduces, the animal consumes (§ 303).—Notes N R pp. 1121, 1123.

14, a. If an animal compound be decompounded, the reunion of the elements into an animal substance requires the agency of both vegetable and animal organization; and, not only so, but nothing can reproduce any given animal compound but the precise part of the same species of animal which gave origin to the part so decompound-

ed (§ 12).—Note R p. 1123.

14, b. Owing to this universal law, by which the animal is rendered so perfectly dependent on the vegetable kingdom, the Creator has given a striking perfection to the grand design in the institution of an invisible world of animalcula for the consumption of that vast proportion of organic matter which is passing through the process of maceration to its elementary state. Thus arrested by these economists of nature, it advances through an ascending series of animals, till, at last, it becomes the food of man (§ 151, 1052).

The foregoing distinction is fundamental in nature; and here, at the very threshold, we are met by a barrier which the chemist and physical philosopher cannot pass from one side, nor the physiologist

from the other (§ 1052).

14, c. I may also say, that it is no small proof of a Creator, that the elements of all combinations which are generated by animals and plants are derived from the inorganic kingdom, which will be allowed to be less productive than the organic. And since, especially, no organic being can generate any elementary substance, nor the elements unite, of themselves, into organic compounds, it follows that the whole was created by a Being of greater power. We can go no farther back than the elements of matter. Here the atheist himself pauses in dismay. They proclaim a God, and reason submits to this

limit of its powers.

I may also propose another, and perhaps greater proof of the error of spontaneous generation. The kingdoms of nature are governed by inherent powers, and the organic possess powers peculiar to themselves; but the existence of matter, whether organic or inorganic, is also indispensable to their respective forces. These forces, therefore, did not create matter; and since matter cannot create matter, and therefore did not create itself, it follows that its associate powers did not create themselves. Whence it is obvious that some greater Power exists by which the powers of nature were created in union with matter (1079 b, 1083, 1085).—Notes Pp p. 1142, Qq p. 1145.

These arguments, therefore, may be taken in connection with those which I formerly adduced for the purpose of exposing the fallacy of the doctrine implied by Carpenter, Pritchard, Fletcher, and others, by assuming that the vital properties exist in the elements of matter, and that, therefore, the elements are capable of arranging themselves into organic beings. (See my Examination of Reviews, p. 37, and

my Notice of Reviews. Also, § 1051, 1052.)

15. Exact analyses are readily made of mineral compounds, and the elements may be recombined into the same or other mineral compounds.

The precise analysis of the most simple organic compound, solid or fluid, as fibrin or albumen, is very difficult, and always liable to doubt.

16. Excepting the earths, plants subsist upon the atmosphere and what it contains (§ 303); but they immediately derive much of their nourishment from decaying organic substances that are incorporated with the soil. But, before such compounds can be appropriated by plants, they must be resolved into their elementary state. They can be taken into the organization of plants only in the condition of mineral substances; and even then the most simple binary compound must be decompounded before organization can begin. All the recombinations, as constituting parts in the vegetable economy, are essentially unlike any substance in the mineral kingdom.

17. If animal organization resolve an organic compound into a mineral condition, such compound is useless in the animal economy (§ 13, 14). There is never present, therefore, in the animal organization, as a part of, or as a source of supply to that organization, any mineral substance (§ 360). Whatever mutations the materials of supply may undergo, they must always exist in an organic state, or be permanently restored to the mineral kingdom.—Notes N R pp. 1121, 1123.

18, a. We learn from the foregoing premises (§ 17), that food does not lose its organic state during the process of digestion; and since it becomes more and more nearly assimilated to the living solids from the earliest action of the gastric juice, it is evident that chemical agencies have no connection with the transformations to which it is

subjected in the alimentary canal (§ 350-376).

18, b. Hence, also, the fallacy of attempting, by chemical analysis, to indicate the proper sustenance of man and animals. "To determine," says Liebig, "what substances are capable of affording nourishment, it is only necessary to ascertain the composition of the food, and to compare it with that of the ingredients of the blood." He then proceeds to a practical application of this principle by setting forth the chief elements of the blood. The difficult subject, also, of identifying hay with the flesh of animals, and all the vegetable substances which enter the human stomach with the various tissues of the body, is so far disposed of as to require no other interposition between the nutriment and its conversion into living animal compounds than the chemical forces. This chemical doctrine is thus set forth by Liebig:

"The most recent and exact researches have established as a universal fact, to which nothing yet known is opposed, that the nitrogenized constituents of vegetable food have a composition identical with that of

the constituents of the blood."-LIEBIG'S Animal Chemistry.

18, c. And such, too, is a common example not only of the assumptions of this writer, but of that positive manner which has inspired such universal confidence (§ 350\(\frac{1}{4}\)-350\(\frac{1}{2}\)). There are, of course, in nitrogenized vegetable food certain combinations more or less analogous to what are called the constituents of the blood, though never the same, and but comparatively few in many that are appropriate as means of nourishment; nor could it be doubtful that the elements of the flesh and blood of animals subsisting on vegetables must exist in their food. But the identity of elements in any given vegetable and animal compounds is very different from identity of compounds, and this, too, with every imaginary latitude of the isomeric and polymeric problems. Nor have any two chemists agreed, as yet, in their analysis of blood, or of any animal compound (§ 1029, 1030,).

But we have from the laboratory most ample admissions of the groundless nature of the preceding statement. Thus, again, Liebig:

"As far as our researches have gone, it may be laid down as a law, founded on experience, that vegetables produce, in their organism, compounds of proteine; and that out of these compounds of proteine the various tissues and parts of the animal body are developed BY THE VITAL FORCE, with the aid of the oxygen of the atmosphere and of the

clements of water.

"Now, although it cannot be demonstrated that proteine exists ready formed in vegetable and animal products, and although the difference in their properties seems to indicate that their elements are not arranged in the same manner, yet the hypothesis of the pre-existence of proteine, as a point of departure in developing and comparing their properties, is exceedingly convenient. At all events, it is certain that the elements of these compounds assume the same arrangement when acted on by potash at a high temperature"!!—Liebig's Animal Chemistry.

Nor is this the end of the contradiction; for we also read in the

same work, that

"We cannot, indeed, maintain that the animal organism has no

power to form other compounds, for we know that it is capable of producing an extensive series of compounds, differing in composition from the chief constituents of the blood" (§ 409, b, and 53, b).

But, if the foregoing quotations be conclusive of the specific inquiries before us, the following admitted facts not only establish the same conclusions, but prove that chemistry is entirely incompetent to any one of its pretensions as to a proximate analysis of the blood, or of other organic compounds, and that it is strictly limited to a mere elementary decomposition; while they also concede the existence of a vital principle as an "immaterial" governing power, wholly different from any attribute of inorganic nature, and therefore render it certain in another aspect, that the chemist, from want of this agent, can, at most, only effect the elementary analysis of organic compounds. Thus, then, the organic chemist:

"If the problem to be solved by organic chemistry be this, namely, to explain the changes which the food undergoes in the animal body; then it is the business of this science to ascertain what elements must be added, what elements must be separated, in order to effect, or, in general, to render possible, the conversion of a given compound into a second or third; but we cannot expect from it the synthetic proof of the accuracy of the views entertained, because every thing in the or ganization goes on under the influence of the vital force, an immaterial agent which the chemist cannot employ at will."—Liebig's An-

imal Chemistry.

18, d. If we now turn to section 409, b, we shall there find that it is in the blood alone that the reputed proximate principles of vegetables are assumed to exist, and that many proximate compounds are allowed by the chemist to be elaborated from the blood to which there is nothing at all analogous in the vegetable kingdom, or even in the blood itself.

This, then, is the sum of the whole subject: 1st. The chemist has his favorite doctrine of digestion, as an important foothold for materialism, forever present, to be extended as far as the obscurities of the subject will admit, and to borrow an apparent confirmation from these predicated assumptions. The absolute amount of that doctrine is thus expressed by Liebig:

"In the natural state of the digestive process, the food only undergoes a change in its state of cohesion, becoming fluid without any

other change of properties."—Liebig's Animal Chemistry.

2d. Now, the food undergoing no other change "in the digestive process" than that of becoming "fluid," it is the easiest matter to find it all in the blood just as it was taken into the stomach,—vegetable as well as animal; while, in so finding it, a pretended confirmation is set up of the "universal fact, to which nothing yet known is opposed, that the nitrogenized constituents of vegetable food have a composition identical with that of the blood," and vice versa. Or, as Liebig also has it, "vegetables produce in their organism the blood of all animals" (§ 350, no. 76).

But, 3d. We are assured by chemists, that nothing is more difficult of analysis than the blood, even as it respects its elementary composition; while it is well known that the analyses of this fluid are always discrepant. Hence the impracticability of instituting unexceptionable comparisons between even the elementary composition of blood and the nitrogenized constituents of plants; while the very nature of the chemical influences exerted upon a vital compound of 17 or 18 elements with a view to its analysis is conclusive of the artificial condition of all the chemical compounds which may be thus formed out of the homogeneous fluid. And so LEHMANN, § 1029, 1030.

Again, 4th. It is finally said that many substances elaborated from the blood are utterly different from any thing discovered in plants, or in the blood itself (§ 409, b). Here, the composition of the organic substances being simple, readily leads to an exposure of the assumptions which have taken refuge under the greater difficulties, and obscurities, and disagreements, attending the analysis of the most complex substance known in nature (§ 53).

18, e. But we shall see, farther on, that the chemical school maintain, through their principal chief, those doctrines of digestion, to suit other hypotheses in organic chemistry, which are fundamentally opposed to each other, and which I shall now arrange in connection, that the reader may see, at a glance, not only the speculative nature of organic chemistry, but the feebleness of the assumption as to the identity of the blood and the nitrogenized constituents of plants Thus:

the constituents of the food Position or transformation arrange themselves in another form, and combine to produce new compounds. It FORCES the new compounds to assume forms ALTOGETH-ER DIFFERENT from those which are the result of the attraction of cohesion when acting freely, that is, without resistance."—LIEBIG'S Animal Chemistry.

M.

"In the natural state of the digestive process, the food only undergoes a change in stituents of food, and destroys its state of cohesion, becoming fluid without any other change of properties."—Liebia's Animal Chemistry.

B.

"The VITAL FORCE CAUSES

"The most decisive expanses of chymistration of attaction which is continually exerted be pendent of the vital force; that it takes place in virtue of a Purely Chemical action, exactly similar to wise, that the ELEMENTS of the constituents of the food

It will be therefore seen by the quotations B and C, that the statement is admitted to be a mere assumption; while it necessarily follows, by adopting either of the contradictory statements, B or C, that the vegetable substances undergo a radical change during the process of digestion, and, therefore, that we cannot find those substances in the blood, but their elements, only, in new and peculiar combinations. The differences, indeed, are probably often much greater than between calomel and corrosive sublimate (§ 3501).

What, also, gives to the whole of this subject its proper interpretation is the parallel which is drawn by Liebig between the assimilation of the most virulent poisons and the most appropriate food, as set forth in Section 350, Nos. 41 and 42. The looseness of the closing sentence of No. 41, abstracted from all the surrounding evidence of hypothesis, is abundantly conclusive of the conjectural nature of the whole of this pretended mathematical demonstration.

There is no difficulty, however, in comprehending the source of the mistake which honest chemists have made in attempting, by chemical analysis, to indicate the proper sustenance of man and ani mals. It lies in a wrong conception of the economy of vegetable life, and thence reasoning from a mistaken coincidence of principles, which exist in the two departments of the organic kingdom in a strikingly modified state, to their more analogous results (§ 10,

13-17).—Notes N R pp. 1121, 1123.

Since, however, plants subsist upon mineral substances, in their elementary state, the chemist may often successfully indicate those inorganic or organic compounds which will yield to any given species of plant (whose general elementary composition may be known) the elements that go especially to its nutritive economy. But, from a fundamental distinction between plants and animals (§ 11, 13-17), it is obvious that no such thing can be done in relation to the latter. better practical proof of this can be wanted than the perfectly indigestible nature of many compounds which contain the requisite elements. Such compounds, upon the chemical philosophy, as I have said, and as admitted by Liebig, include many virulent poisons in the vegetable kingdom, and many inorganic substances whose binary compounds embrace numerous elements. We need not, indeed, go any farther than the recent experiments by Dr. Beaumont upon the varieties of food, as will be subsequently noticed (366), and Magendie's analogous experiments with the food of animals,* to show that the whole of this subject must be left to natural experience.

Nor does it appear to have occurred to the chemical physiologist, in the foregoing inquiries, that the elementary composition of animals is greatly alike, at least in all mammalia. It should follow, therefore, upon the chemical philosophy, that the practical distinctions should not exist between the food of man and animals, but that a common diet should be as universally adapted as atmospheric air. To this conclusion it may be also added, that the same chemical philosophy refers chymification to a purely chemical process; or, in the language of Liebig, "it takes place in virtue of a purely chemical action, exactly similar to those processes of decomposition or transformation which are known as putrefaction, fermentation, or decay."— Animal Chemistry, p. 16. And since, therefore, chymification is "independent of the vital force" (ibid.), and as chemistry identifies the gastric juice of man and quadrupeds, and even the chyme, it is obvious that chemistry can predicate nothing, upon this subject, of any difference in the vital constitution of man and animals (§ 409,

350, d).

19. In respect to their general structure, inorganic bodies are homogeneous, organic beings heterogeneous. This applies as well to the elementary constituents in their modes of combination as to the compound structure of the whole being. Each particle of a mineral compound is as much a whole as the greater mass, and has the same combination of elements. Each element is as perfect as the compound conditions. Animals have muscles, glands, nerves, vessels, &c., with an endless variety in the elementary combinations in the same individual. All these parts are necessary to make a whole, and depend, mutually, upon each other for their existence. The same

^{*} See Medical and Physiological Commentaries, vol. i., p. 697, &c. † See my article on the foregoing subject in the Boston Medical and Surgical Journal December 27, 1843.

general principle is applicable to plants. Nevertheless, apparent exceptions occur in both animated kingdoms, as in parts of many plants and of polypi. But, in these instances, each part possesses essential-

ly the whole apparatus of organic life.

20. Organic beings grow from within by interstitial deposition of molecules derived from the blood or sap, according to the exact nature of each part. Inorganic bodies do not grow, but increase only by a superficial juxtaposition of parts, which may, also, be wholly unlike the original crystal, or other nucleus, in their elements.

In the process of growth and nutrition the new material is conveyed within from without, and subjected to many specific changes, till it is resolved into one homogeneous fluid. Atmospheric air is also indispensable to all organic beings. There is nothing analogous in the inorganic world; while these, and an endless series of other facts, establish the similitude of the organic life of plants and animals.

21. A peculiar action of certain agents upon the whole organism of plants and animals, called *vital stimuli*, entirely unlike the action of chemical agents, is necessary to the growth and existence of organic beings. They are both internal and external, and give rise to all the phenomena in organic life, and maintain the whole in one exact condition; while the action of agents upon inorganic, or on dead organic, substances, does not elicit one of these multifarious phenomena (§ 74, 188½).

22. Every part of an animal or vegetable is forever distinguished by the same vital phenomena and physical results; and the action of vital stimuli is forever the same on each part, respectively, but, like the vital phenomena and physical results, different in each; the whole being liable to invariable modifications at different stages of life, and according to temperament, and according, also, to every

other modifying influence.

23. Unlike inorganic bodies, organic beings require the coexist-

ence of solids and fluids in their composition.

24. All organic beings have the power of generating motion within all their parts. Mineral compounds have no such endowment. If motion take place in their internal constitution, it depends upon influences which have no existence in living beings. Nor is this all; for motion is always generated in living beings by the operation of a power implanted in their constitution, and this power is brought into action by the mind, and by internal and external physical agents.

25. The solids and certain fluids of organic beings act upon each other. But the fluids act only upon the organic properties of the solids, while the solids transmute the most important fluid into their own substance. The stimulant action of the blood upon the organic properties, and the reaction of the solids upon the blood, are designed for a common end. The concurrence of the whole fabric is necessary to these, as to all other, results. There is nothing analogous in the mineral kingdom.

26. When external or internal agents produce motion in organic beings, they do not affect the composition, in the natural state. It is

quite otherwise with inorganic or dead organic compounds.

27. Organic beings are perpetually subject to a vital decomposition and removal of old parts, while the old are exactly replaced by new

ones. It is essential to mineral compounds that they remain without change. Any disturbance of their molecules deranges their structure or composition.

While, therefore, inorganic compounds are forever the same, organic beings are subject to an unceasing loss of identity as respects

their present component parts.

28. The external forms of plants and animals are variously and greatly contradistinguished from those of inorganic bodies. condition of one, also, is uniform; that of the other, even when crystalized, is variable.

29. "The only character," says Muller, "that can be possibly compared in organic and inorganic bodies, is the mode in which symmetry is realized in each; that is to say, the character which minerals possess in their state of crystalization." Yet there is not, in this respect, the slightest analogy; since no true organic compound ever approaches the condition of a crystal. Here we may trust the authority of Liebig, who says of the "vital principle of the animal ovum, as well as the seed of a plant," that,

"Entering into a state of motion or activity, it exhibits itself in the production of a series of forms, which, although occasionally bounded by right lines, are yet widely distinct from geometrical forms, such as we observe in crystalized minerals. This force," he goes on, "is the

vital force, vis vitæ, or vitality."

- 30. The foregoing considerations, each and all (§ 8-29), demonstrate a radical difference between the forces and laws of organic and inorganic beings, and a remarkable modification of such as are common to plants and animals. But, as the institutions of organic life lie at the foundation of medical science, they should be still farther sought in the contradistinctions between the organic and inorganic kingdoms, and in those diversified phenomena which indicate a common but modified government of animals and plants. All organic beings possess in common the most essential conditions of life, though existing in the two great departments of living nature under specific modifications or varieties; not, however, very dissimilar, but intimately connected by a gradation of analogies, as we descend along the chain of either, till we arrive at their more absolute connecting link in the lowest being of one and the other. Other conditions are superadded to the nobler department, which, with the differences of structure and the modifications of their common properties of life, and their modes of subsistence, distinguish the two living kingdoms from each other.
- 31. Physiology may be divided into, 1st. The composition of organic beings; 2d. Their structure; 3d. Their properties; 4th. Their functions; 5th. Modifications of properties and functions which arise from sex, temperament, climate, habits, age, &c.; 6th. The relations of organic beings to external objects; 7th. Death.

These several topics will be considered with a special view to the

great principles which form the Institutes of Medicine.

FIRST DIVISION OF PHYSIOLOGY.

COMPOSITION.

32. The principal object contemplated by this work in ascertaining the facts relative to the composition of organic beings is to settle the principles and laws upon which such beings are constituted, by tracing them out in the fundamental conditions of organic matter.

33. Composition is subdivided into ultimate or elementary, and the

proximate parts; the latter being compounded of the former.

34. Of the sixty-six known elementary substances, the following seventeen have been found in the composition of plants: carbon, oxygen, hydrogen, nitrogen, potassium, calcium, iron, manganese, phosphorus, sulphur, silicium, magnesium, aluminum, chlorine, sodium, iodine, bromine.

35. The same elements (34), with the addition of fluor, and the probable exception of aluminum, occur in animals. Arsenic is also often found in man.* Although animals are exposed to various sources from which other elements might be derived, they reject every other elementary principle; or, rather, are incapable of their assimilation.—Notes N R pp. 1121, 1123.

36. The foregoing coincidence in the common nature of the elements of plants and animals supplies no small proof of the peculiar properties and laws of organic beings. Others, however, more striking, lie at the foundation, and form, also, contradistinctions with the

inorganic world.

37. Animal and vegetable substances are mostly composed of carbon, oxygen, hydrogen, and nitrogen, four out of the sixty-six elements that go to the formation of inorganic compounds. The main bulk of plants, indeed, such as the cellular and vascular tissues, is probably composed of carbon, hydrogen, and oxygen alone, as the essential elements; though nitrogen is indispensable to many of the products of vegetable organization, and Liebig says it is found in all parts of a plant (§ 62, f, note). The three or four indispensable elements compose 90 or more parts of 100 of all the soft textures of animals, and of all plants. These are selected, universally, by the vegetable kingdom, as if by instinct. This circumstance increases greatly the force of the conclusion in the foregoing section (§ 36).

38. The elements of mineral compounds are always united in a binary manner; those of organic in a ternary, quaternary, &c., being always intimately blended with each other. This distinction involves an absolute difference in the powers and laws of the two kingdoms.

39. No two elements, therefore, can form a true organic compound. The rare exceptions which have been made by the chemists are not organic substances, nor can they be rendered such by the animal organization. They belong to the mineral kingdom, from which they cannot be elevated but by the properties of vegetable life (§ 14, 16, 17).

All mineral compounds may be resolved into their elements, which are as perfect minerals as when united. Indeed, the most natural con-

dition of a mineral is the state of a simple element.

^{*} Whence come the fluor and the arsenic, unless through plants? (§ 14-18.)

40. What, therefore, is so fundamental in organic beings as expressed in sections 38 and 39, and universally admitted, allows of no introduction of powers, principles, laws, &c., which shall conflict with the powers and laws upon which the simplest organic compound is constituted. In the progress of this work it will be seen that this position is every where substantiated. Unity and harmony prevail throughout each department of nature, respectively; and while the powers and laws of the organic are as fully contradistinguished from those of the inorganic kingdom as are their physical and all other attributes, we shall find that the former are apparently embarrassed by a great diversity of phenomena as manifested in health and disease, but that, in reality, all the variety goes to the conclusion that the fundamental principles are the same throughout (§ 638, 733, d).

41. Again, we may suppose at least some 20,000,000 of distinct organic compounds in the various species of plants, and some 30,000,000 more in the animal kingdom, formed mostly out of four elements (§ 37), while these same elements yield scarcely a dozen combinations in the

mineral kingdom.

42. The foregoing organic compounds are formed in each individual, respectively, out of one common homogeneous fluid, composed of about seventeen elements.* No chemical hypothesis can interpret this universal characteristic of the organic kingdom; while all the relative facts of inorganic chemistry are totally opposed to this almost endless and undeviating variety of new combinations out of a common fluid, according to the species of animal or plant, and according to the nature of every particular part. If chemical agencies operated, there would be no uniformity in any secreted product at any two successive moments (§ 741, b, 1052).

It is one of the frequent concessions of the distinguished chemico-

vitalist, Müller, that

"The opinion that the component principles of the organs exist in the blood in their perfect state cannot be possibly adopted. The components of most tissues, in fact, present, besides many modifications of fibrin, albumen, fat, and ozmazome, other perfectly peculiar matters, nothing analogous to which is contained in the blood." "Even the fibrin of muscle cannot be considered identical with the fibrin of the liquor sanguinis."—MÜLLER.—So, also, LEHMANN, § 1029-1031.

John Hunter also laid down the following doctrine, as expressed by

his editor, Mr. Palmer:

"It is highly probable that the different proximate principles of vegetable and animal substances hold different ranks in the scale of organized substances, in the same manner that one animal ranks higher in the scale of organized beings than another."—HUNTER.

And thus Liebig, as a *vitalist*, in opposition to himself, as a *chemist*: "In that endless series of compounds, which begins with carbonic acid, ammonia, and water, the sources of the nutrition of vegetables, and includes the most complex constituents of the animal brain, there is no blank, no interruption. The first substance capable of affording nutriment to animals is the last product of the creative energy of vegetables."—Liebig's Animal Chemistry.

* It is now conceded by physiologists, generally, that the chyle, lymph, and blood, are each, severally, as expressed by Wagner, "homogeneous fluids, with certain poculiar corpuscles mixed with them."—See Wagner's Elements of Physiology, p. 250. London, 1842.

43. Although it be generally true that it is the wonderful province of organization to elect only four elements from the homogeneous fluid (§ 42) in the formation of organic compounds, yet there are some compounds which embrace a greater number, though unlike the elements of inorganic compounds, in intimate union with each other (§ 38). The blood, indeed, has not less than seventeen or eighteen elements thus united; a circumstance in itself conclusive that other powers than the chemical must preside over the elaboration of the very limited number of elements that go uniformly to the formation of all other organic compounds. And, although the metallic and earthy substances form no part of the essential organs of life, they are yet vitally united with the indispensable organic compounds in particular parts, and are elaborated from the blood or sap by those parts only, and with an astonishingly relative proportion to the other elements, as sulphur by the brain, phosphate of lime by the bones, fluate of lime by the teeth, phosphate of magnesia by wheat, silex by the stem of wheat, and by the skeletons of many poriferi, &c. We shall not regard these substances as accidental, or as introduced by a physical process, but, as contributing a subordinate part with the essential organic elements toward the perfection of an unfathomable system of Designs, whose moving power is only short of the Creative Energy, in being substituted for that Great First Cause, with limitations that chain it to the fulfillment of secondary ends (§ 847).

44. Organic compounds are forever the same, in health, in any given part of any species of being at each stage of existence, but liable to be more or less modified in an exact manner at the several stages

(§ 153–159).

And so of disease. The same morbid state of any given part, cateris paribus, always produces the same modifications of the organic compounds of which it may be composed, the same alterations of the secreted fluids, and the same new formations. All this is distinctly seen in the phases of scrofula, in small-pox, cow-pox, lues, measles, hydrophobia, &c.

It is opposed to all facts, that any chemical influences can decompound a fluid composed of seventeen or eighteen elements, not only in the exclusive manner represented in the last section, but according, also, to the exact vital constitution or vital modification of each part.

45. Nevertheless (§ 44), the general composition of animals is the same, whether they subsist upon grass, or flesh, or whatever be the nature and variety of the food. So of the chyme, the chyle, and the blood. There is nothing in chemistry that will throw any light upon

these coincidences (§ 18, 409).

46. Contrary to what has been seen of the variety of organic compounds out of four simple elements (§ 41), only a few hundred, at most, of distinct inorganic compounds can be formed out of the 66 elements which compose the mineral kingdom (§ 37). Those few compounds, however, make up the great mass of the globe, while the organic are only scattered over its surface. Nor is there a globe in the universe that would not be as worthless as space, did it not administer to the purposes of life.

47. Different combinations of carbon, oxygen, hydrogen, and nitrogen, constitute, main'y, the whole vegetable and animal materia medi-

ca; while their inorganic compounds do not contribute on remedial

agent of any importance.

48. It is evident that the four principal elements of organic compounds combine not only in different proportions, but so variously, in respect to the proportions, among themselves, as to bewilder the imagination (§ 41). Chemistry can give us no light upon these subjects but what is purely analytical; while, in respect to their mineral compounds, the same elements unite only in a small number of proportions, upon which chemistry throws its light with a brilliancy that may be said to penetrate the unfathomable recesses of their organic compounds. This fundamental distinction is necessarily conceded; and it were well for science if chemistry did not overstep the limit. But, the chemist shall always speak for himself. Thus Liebig:

"6 eq. tartaric acid, by absorbing 6 eq. oxygen from the air, form grape sugar, with the separation of 12 eq. carbonic acid. We can explain, in a similar manner, the formation of all the component substances of plants, which contain no nitrogen, whether they are produced from carbonic acid and water, with separation of oxygen, or by the conversion of one substance into the other, by the assimilation of oxygen and separation of carbonic acid. We do not know in what form the production of these constituents takes place. In this respect the representation of their formation which we have given must not be received in an absolute sense, it being intended only to render the nature of the process more capable of comprehension. But, it must not be forgotten, that, if the conversion of tartaric acid into sugar, in grapes, be considered a fact, it must take place under all circumstances in the same proportions"!—Liebig's Organic Chemistry applied to Physiology.

The reader should never lose sight of the foregoing hypotheses and admissions. They should be ever ready to chasten his credulity as to the chemical interpretation of every organic compound. They stamp the whole "science of organic chemistry," in its synthetical aspects, as one of pretension, and unworthy the confidence of an intel-

ligent mind (§ $350-350\frac{3}{4}$).

And this is farther confirmed by the statements in the two next

following sections.

49. "The particles of matter," says Liebig, "called equivalents in chemistry, are not infinitely small, for they possess a weight, and are capable of arranging themselves in the most various ways, and of thus forming innumerable compound atoms. The properties of these compound atoms differ in organic nature, not only according to the form, but, also, in many instances, according to the direction and place which the simple atoms take in the compound molecules.

"When we compare the composition of organic compounds with inorganic, we are quite amazed at the existence of combinations in one single molecule, of which ninety or several hundred atoms or equivalents are united. Thus, the compound atom of an organic acid of very simple composition, acetic acid, for example, contains 12 equivalents of simple elements; 1 atom of kinovic acid contains 33; 1 of sugar, 36; 1 of amygdalin, 90; 1 of stearic acid, 138 equivalents. The component parts of animal bodies are infinitely more complex even than these."—Liebig's Organic Chemistry, &c.

50. "Inorganic compounds differ from organic in as great a degree

in their other characters as in their simplicity of constitution. Thus, the decomposition of a compound atom of sulphate of potash is aided by numerous causes, such as the power of cohesion, or the capability of its constituents to form solid, insoluble, or, at certain temperatures, volatile compounds with the body brought into contact with it; and, nevertheless, a vast number of other substances produce in it not the slightest change. Now in the decomposition of a complex organic atom there is nothing similar to this."—Liebig's Organic Chemistry &c.

51. "An essential distinction between organic and inorganic compounds is, that in organic products the combining proportions of their elements do not observe, as in mineral compounds, a simple arithmetical ratio."

52. An interesting corollary flows from the foregoing facts (§ 22, 41-50), namely, that all animal and vegetable poisons, all remedial agents of an organic nature, and all the varieties of food, depend upon the modes and proportions in which three or four simple elements unite with each other. It is evident, also, from § 41, that no two remedial agents generated by different species of plants or animals, however similar, can be exactly alike in their morbific or remedial virtues. Hence the differences among cathartics, emetics, &c. composition, especially of the sap, also varies more or less at the different ages of plants and at different seasons, and also from unhealthy conditions, so will corresponding differences arise in their remedial and morbific virtues. In all the cases, however, the characteristics of organic products as vital agents are uniformly the same under any given condition of the organic being; and so of each simple element, and of the physiological effects of all vital agents (§ 1881, d). The precise natural or morbid states of the organic properties lie at the bottom of the whole philosophy, since these properties, through their instruments of action, combine the elements exactly according to their existing state (\S 650, 741 b).

53, a. From the facts now stated (§ 38-51), it is evident that the organic chemist can do no more than effect an analysis of organic compounds. He can only present each simple element by itself, without the possibility of acquiring a knowledge of the modes and

proportions in which they combine with each other.

53, b. So, also, if the aggregate compounds, such as blood, sap, muscle, gastric juice, &c., be, in reality, made up of more simple compounds, or "proximate principles," by the union of compound atoms, chemistry can give us no information as to the conditions in which they naturally exist. Those combinations which are most alike are different from each other in every distinct part of the organic being, and different in the same parts of distinct species. This is so from the first development of the germ; and what is then begun is perpetuated through the life of the individual, and transmitted to all succeeding generations (§ 63-81, 155). The differences, as we have seen, result from the different proportions in which some three or four simple elements are united together, and from the proportions of different compound atoms which may enter into the entire combination, and from the manner in which they and their elements are combined among themselves. It must be obvious, therefore, that we can never reach the secret of these combinations. We should necessarily expect, even from the shades of elementary distinctions, that chemistry would confound and even identify many compounds that are totally unlike in their nature. And this it actually does, in presenting to us sugar, vinegar, starch, gum-arabic, wood, &c., as the same substance; and in identifying pus and cheese, and, again, the albumen of eggs, lymph, mucus, and the product of certain cancerous affections. Nor is there generally any agreement among the chemists in their analyses of organic compounds. It is as true now, as when Bostock (a chemical physiologist) affirmed, that "every subsequent attempt to discover the elements of organized substances differs

more or less from those that preceded it" (§ 1029, 1030).

The moment chemical agencies begin their operation, artificial transformations necessarily ensue, and the nature of the organic compound is changed in a corresponding manner. A large proportion of the resulting products are perfectly new formations, particularly all the binary compounds (§ 38, 39). Nor can there be any doubt that the reputed "proximate principles" are intimately incorporated in any given compound, and have no such separate existence as chemistry teaches. It lies at the very basis of chemistry, that all the elaborations are the artificial results of affinities which have been set in motion by the agents employed, and which are employed for that very purpose. This I have already endeavored to demonstrate in the Medical and Physiological Commentaries (vol. i., p. 674-682), even so far as to show that urea may not be formed by the kidneys, but is the result of spontaneous changes after the elaboration of urine, as it is of artificial influences (§ 54, a). But, attentive observation will generally detect the chemist in the admission of facts which are subversive of his speculative doctrines (§ 18, 350); and so it is in the case before us. The admission covers the whole ground as to the pretensions of organic chemistry beyond the most simple elementary analysis. Thus,

53, c. "Were we able to produce taurine and ammonia directly out of uric acid or allantoine, this might perhaps be considered as an additional proof of the share which has been ascribed to these compounds in the production of bile. It cannot, however, be viewed as any objection to the views above developed on the subject, that with the means we possess, we have not yet succeeded in effecting these transformations out of the body. Such an objection loses all its force, when we consider that we cannot admit, as proved, the pre-existence of taurine and ammonia in the bile; nay, that IT IS NOT EVEN PROBABLE that those compounds, which are only known to us as the products of that fluid. By the action of muriatic acid on bile, we, in a manner, force ITS ELEMENTS TO UNITE IN SUCH FORMS as are no longer capable of change under the influence of the same re-agent."

-Liebig's Animal Chemistry.

By the admissions, also, in § 18, 42, and 350, it will be seen that the Utopian nature of organic chemistry is equally established in all its pretensions by its own founders and advocates (§ 1030).

54, a. Organic substances alone undergo fermentation and putrefaction; and this shows us, also, in the language of Tiedemann, that "even when the life of organic bodies is extinct, we should consider the qualities which they possess, from the time of death to the complete resolution of organization, as the result of the vital powers which have been active in them."

This obvious principle conducts us at once to the whole philosophy of those numerous transformations of which organic compounds are susceptible from chemical agencies, while they still retain their elementary combinations, and appear under uniform aspects when subjected to the same chemical influences, and often analogous to the natural condition of the compound. "It is the power of formation," says Tiedemann, "which, after the extinction of the individual life of organized bodies, renders the organic matters, separated from their organization, capable, provided they have not been reduced to their elements by external physical or chemical actions, of assuming new and more simple forms, according to the diversity of external influences, such as heat, light, water, &c., which determine them in taking on this new form. This power appears, therefore, to be a property inherent in organic matters in general, rendering them able to take other more simple configurations when detached from the combinations of living bodies" (§ 1029, 1030).

Some organic compounds undergo transformations of the foregoing nature as soon as separated from the organic being. The homogeneous blood is immediately reduced into three principal compounds, which have no natural existence as such. Nor is this all; for there is a fundamental change among the elements and the compound atoms of the entire mass. The changes arise from the loss of the vital properties, and the subsequent operation of chemical influences. Such, too, is the constitution of organic compounds that there may be a remarkable uniformity in the resulting products when the same chemical agents operate upon any given compound; as exemplified in the various transformations to which sugar is liable, and as seen in the uniform production of morphia, narcotina, quinia, cinchonia, &c.

54, b. It is obvious, however, from the premises which I have set forth, that chemistry can, at most, present but a few compounds as apparently distinct from each other in their elementary composition; for, although there are many millions of these distinct combinations in organic beings (§ 41), they commonly possess such analogies that chemistry is obliged to confound all but a few which have strong characteristics. These few, which are denominated proximate principles, are supposed by the chemist to make up the entire composition of organic beings. But, a greater proportion even of these few are so inscrutably different from each other in their elementary combinations, that they are classed under common denominations, not only for the foregoing reason, but on account of certain resemblances in their physical properties; while it is by these last, and by their differences in results as vital agents, we come to know that broad distinctions may exist among them. Such, for example, are the various acids, oils, resins, &c.

55. All organic substances, while endowed with life, resist the decomposing influences of all surrounding agents. All inorganic com-

pounds yield to these influences.

56. As soon as organic beings are dead, the very agents that had contributed to their growth and nourishment now become the causes of breaking up their elementary combinations, and with a rapidity unknown in the ordinary decomposition of mineral compounds. In the

former case, it is allowed by Liebig, that the "VITAL PRINCIPLE OP-POSES to the continual action of the atmosphere, moisture, and temperature, upon the organism, a resistance which is in a certain degree invincible."

57. In the seed and ovum the properties of life are in a state of action which maintains their elementary combinations against the chemical forces. They resist degrees of cold which operate destructively upon their composition when their life is extinct. Those agents, too, as heat and moisture, which speedily resolve the egg and seed, when deprived of life, into their ultimate elements, will in the same degrees of intensity develop from the germ, when alive, a perfectly organized being. In the former case the operation of the principle of life is generally mistaken for "a force in a state of rest." Thus, Liebig:

"In the animal ovum, as well as in the seed of a plant, we recognize a certain remarkable force, the source of growth, &c., a force in a state of rest."—Liebig's Animal Chemistry, first sentence. See,

also, my Examination of Reviews, p. 7-28.

58. It follows, therefore, that the power which resists the decomposing forces and agents in living beings combined the elements of such beings, and that death is an extinction of that power. The chemical forces can have no connection with the combinations, since they are held together by a power in direct opposition to chemical influences.

What, therefore, unites the elements and maintains them against the action of chemical agents, being the fundamental power, must necessarily preside over all the processes and results to which organic

beings are liable.

59. "The elements of dead organic matter," says Liebig, in his Organic Chemistry, "seem merely to retain passively the position and condition in which they had been placed." "The atoms exist only by the vis inertiæ of their elements." So, also, Mülder, § 350\(\frac{3}{4}\), n, and other chemical physiologists. This shows that the original union is effected by other powers than the chemical, which, otherwise, would still operate after death, and prevent decomposition. We also thus learn why dead organic compounds so readily undergo fermentation and putrefaction, and from the slightest influences. All of which, indeed, appears to be abundantly conceded by the chemical philosopher when he yields to the force of facts. For what can be more ample than Liebig's affirmation, that

"The VITAL FORCE is manifested in the form of RESISTANCE, inasmuch as by its presence in the living tissues, THEIR ELEMENTS acquire the power of withstanding the disturbance and change in their form and composition, which external agents tend to produce; a power, which, as chemical compounds, they do not possess."—LIEBIG'S Animal Chem-

istry.

And yet again may I press into the service of truth the organic chemist, when he temporarily loses sight of the laboratory, and contradicts those speculations which impart to his writings the zest of novelty. In his *Lectures* for the winter of 1844, Liebig appears to have been alarmed for the safety of his empire, and we have here an unusual amount of "vitality."

The work on Animal Chemistry applied to Pathology and Thera-

peutics was more of a distillation from the laboratory than its predecessor, Organic Chemistry applied to Physiology; and, as many of the most eminent physiologists in Europe, who were inclined to mingle chemistry with vitalism, were nauseated by the dose which was last administered, Liebig came out in his Lectures with the following placebo for the vitalists, and the chemico-vitalists. Were it not contradicted by the lecturer, it should place him in the very front rank of vitalism. The doctrines are of the most fundamental nature, and lie at the basis of these Institutes, and of my "Medical and Physiological Commentaries." It will be seen that they are strictly relative to my present subject, and inculcate all that the most transcendental vitalist can desire as to the distinct nature of the vital principle, its full control over the processes of life, its extinction at death, and an absolute distinction between vital and chemical processes and results, while those processes and results are, respectively, referred to forces of a totally distinct nature. Thus:

"After the EXTINCTION of the vital principle," says Liebig, "in organic atoms, they maintain their form and properties, the state into which they have been brought in living organisms, only by reason of their inherent inertia. It is a great and comprehensive law of matter, that its particles possess no self-activity, no inherent power of originating motion, when at rest; motion must be imparted by some external cause; and, in like manner, motion once imparted to a body can

only be arrested by external resistance.

The constituents of vegetable and animal substances having been formed under the guidance and power of the vital principle, it is this principle which determines the direction of their molecular attraction. The vital principle, therefore, must be a motive fower, capable of imparting motion to atoms at rest, and of opposing resistance to other forces producing motion, such as the chemical force, heat, and electricity. We are able to reliquefy and redissolve albumen, after it had been coagulated by heat, but the vital principle alone is capable of restoring the original order and manner of the molecular arrangement in the smallest particles of albumen. Coagulated albumen is again converted into its original form, it is transformed into flesh and blood in the animal organism.—Notes N R pp. 1121, 1123.

"In the formation of vegetable and animal substances, the vital principle opposes, as a force of resistance, the action of the other forces,—cohesive attraction, heat, and electricity,—forces which render the aggregation of atoms into combinations of the highest order

impossible, except in living organisms.

"Hence it is, that when those complex combinations which constitute organic substances are withdrawn from the influence of the vital force,—when this no longer is opposed to the action of the other disturbing forces, great alterations immediately ensue in their properties, and in the arrangement of their constituents. The slightest chemical action, the mere contact of atmospheric air, suffices to cause a transposition of their atoms, and to produce new arrangements; in one word, to excite decomposition. Those remarkable phenomena take place which are designated by the terms fermentation, futrefaction, and decay; these are the processes of decomposition, and their ultimate results are to reconvert the elements of organic bodies into that state in which they exist before they participate in the processes of life."

The reader, however, will be more astonished to learn that he has not discovered, amid the multitude of conflicting statements and doctrines, a passage in the work on Animal Chemistry which, even more than the preceding, identifies "the Reformer" with the most exclusive vitalists, and completely annuls all his chemical and physical speculations as to organic life, and his radical distinctions between plants and animals (§ 350, nos. 12, 15, 20). It will be also seen with what pretense he has been denominated "the Reformer," and "the author of a new and the greatest era in physiology." The extract inculcates the doctrines of an independent vital principle, its identity in plants and animals, the action of stimuli upon that principle, its susceptibility of influences from the nervous power in animals, the absence of that influence in plants, and the dependence of all organic processes and results, equally in plants and animals, upon that principle.

Now these are exactly the doctrines which are also fundamental throughout the Medical and Physiological Commentaries and these Institutes. They are relative to the constitution and processes of organic beings as a whole, while the foregoing quotations from Liebig's Lectures comprehend the principles by which I have interpreted the elementary condition of organic bodies. Thus our author:

"The activity of vegetative life manifests itself, in vegetables, with the aid of external influences; in animals, by means of influences produced within the organism. Digestion, circulation, secretion, are, no doubt, under the influence of the nervous system; but the force which gives to the germ, the leaf, and the radical fibres of the vegetable the same wonderful properties, is the same as that residing in the secreting membranes and glands of animals, and which enables every animal organ to perform its own proper functions."—Liebic's Animal Chemistry.

60. "The diversity of the transformations and of the resulting products," says an able advocate of Liebig's physical doctrines of life, "indicate most certainly the complexity of an organic product" (§ 41). "The metamorphoses which occur after organic substances are removed from the influence of the vital force, constitute a separation, or splitting up into new and less complex compounds" (§ 54).—MR. ANCELL, in London Lancet, Nov. 26, 1842.

Thus, again and again, does the chemical physiologist unavoidably concede that the elements of organic beings are held together by a vital principle, and, therefore, that they are originally united by that

principle.

Vitalism becomes established in all its aspects, even in what has been denominated "transcendental vitalism," when it may be shown that the elements of organic beings are, in the language of Liebig, "united by a peculiar mode of attraction, resulting from the existence of a power distinct from all other powers of nature, namely, a Vital Principle;" since, as I have said, the powers and laws which regulate the composition must be at the foundation of all the subsequent results. Concessions of fundamental principles overthrow all opposing "facts," and all secondary doctrines of a conflicting nature. These, therefore, may be advantageously connected with demonstrations of the truth. There are few intelligent minds that do not rightly appreciate those grand phenomena of Nature which conduct us to

a knowledge of her fundamental laws, or do not incidentally betray their conviction of the right, however the enticements of fame may beguile them into ingenious substitutions. I shall, therefore, as on all former occasions, continue to bring to the aid of my conclusions the powerful concessions of the most eminent men who belong to the adverse schools in organic philosophy. It is manifest that such authorities must weigh with the force of demonstration, since it is obvious that their admissions can flow only from convictions that have been obtained in the school of Nature. Among the most illustrious of the adverse school is Liebig, and standing intermediate is the profound and erudite Müller. And having thus referred again to this great philosopher, I will not lose the opportunity of obtaining from him an important contribution to the doctrines of vitalism as they relate to the very composition of organic beings, and in which he institutes a broad contrast between the affinities which unite the elements of organic and inorganic compounds. Thus:

"Chemical substances," says Müller, "are regulated by the intrinsic properties and the elective affinity of the substances uniting to form them. In organic bodies, on the contrary, the power which induces, and maintains, the combination of their elements, does not consist in the intrinsic properties of those elements, but in something else, which not only counteracts those affinities, but effects combinations in direct opposition to them, and conformably to the laws of its

own operation."—MÜLLER, Elements of Physiology, p. 4.

Liebig, also, variously inculcates the same great principle. Take, in the first place, a demonstration the converse of Müller's. It is the

last paragraph in the work on Organic Chemistry. Thus:

"The same numerous causes which are opposed to the formation of complex organic molecules, under ordinary circumstances, occasion their decomposition and transformations when the only antagonist power, the vital principle, no longer counteracts the influence of these causes. New compounds are formed in which chemical affinity has the ascendency, and opposes any farther change, while the conditions under which these compounds were formed remain unaltered."

Again, we are informed by this chemist, that

"The equilibrium in the chemical attractions of the constituents of food is disturbed by the vital principle, as we know it may be by many other causes. But the union of the elements, so as to produce NEW COMBINATIONS and forms, indicates the presence of a peculiar Mode of attraction and the existence of a power distinct from all other powers of nature, namely, the vital principle." "If the food possessed life, not merely the chemical forces, but this vitality would offer resistance to the vital force of the organism it nourished." "The individual organs, such as the stomach, cause all the organic substances conveyed to them, which are capable of transformation, to assume new forms. The stomach compels the elements of these substances to unite into a compound fluid for the formation of blood."—Liebig's Organic Chemistry, p. 356, 357, 346, 384.

61. It is a remarkable characteristic of organic beings that they are composed chiefly of combustible substances, properly so called, and a supporter of combustion; with the principal exception of that anom-

aly in the inorganic kingdom, nitrogen gas (§ 37).

62, a. The general introduction of nitrogen gas into the constitution of animal compounds, and into many of a vegetable nature, while it is excluded from mineral compounds, is one of the most striking distinctions between the two kingdoms of Nature. Upon that distinction I have founded an argument, in my Essay on the "Philosophy of Vitality," in proof of the difference in the powers and laws by which the two kingdoms are governed. It appears also appropriate to this work

that the proof should be here introduced.

62, b. I have said in the foregoing Essay, that it is abundantly evident that living beings are endowed with properties which protect their elementary composition against all those decomposing agencies which are perpetually separating the elements of all mineral com-This shows that the properties, by which the elements of living beings are united, are utterly different from such as combine the elements of inorganic compounds. Nevertheless, the living organization is undergoing a systematic change, a perpetual decomposition, surpassing any mutations that are in progress in the surrounding world. These decompositions are, also, of a peculiar nature, governed by established laws, various in different parts of the same individual, yet forever the same in any given part (§ 44). I shall not stop to show how the old are replaced by new materials, and how the processes go on pari passu, and in opposition to all the philosophy which chemistry teaches, but only say that the decompositions must be effected by properties as peculiar to the living compound as are the results; and that these results conspire with the peculiar modes in which the elements are combined in proving the existence of specific properties, which are the common cause of all the harmonious phenomena of living beings (\S 38–42).

62, c. When, however, the organic being dies, a new order of decomposition begins, eminently of a chemical nature, and in forcible contrast with that which concerns the vital process of renewal. This is due to the special element, nitrogen gas, which may be called the principle of dissolution. Wherever present, it gives rise to transformations and disunion of all the other elements after the properties of life have lost their sway. The moment these cease, chemical decomposition begins,—confusedly, violently; and such are the nature and combinations of the elements, that their disruption would go on with no other contribution from surrounding agents than water alone. Hence the more rapid transformations and dissolution of animal than of vegetable tissues, and of sap and other substances which are gen-

erated by vegetable organization.

62, d. Liebig says of nitrogen gas, that "there is some peculiarity in its nature, which gives its compounds the power to decompose spontaneously with so much facility. Now, nitrogen is known to be the most indifferent of all the elements. It evinces no particular attraction to any one of the simple bodies, and this character it preserves in all its combinations; a character which explains the cause of its easy separation from the matter with which it is united." And again, "When those substances are examined which are most prone to fermentation and putrefaction, it is found that they are all, without exception, bodies which contain nitrogen."—Liebig's Organic Chemistry applied, &c., p. 241.

62, e. In the inorganic kingdom, nitrogen is mostly confined to the

atmosphere, where it probably exists in a state of simple intermixture with oxygen. "All bodies which have an affinity for oxygen abstract it from the atmosphere with as much facility as if the nitrogen were absent altogether;" and we have striking examples of the disposition of nitrogen to separate from its compounds, "in the easy transposition of atoms in the fulminating silvers, in fulminating mercury, and in all fulminating substances," whose ready explosion is owing to the presence of nitrogen. "All other substances," says Liebig, "containing nitrogen acquire the same power of decomposition when the elements of water are brought into play."

62, f. Now the foregoing characters belong to nitrogen only as it exists in inorganic or in dead organic compounds, while the former, also, are artificial, or due to accidental causes. In living beings, where it abounds,* it adheres to its associated elements with a tenacity which no agent can impair till it destroys the life of the part; or, in other words, till it destroys those vital properties by which the elements were truly united. It is then, however, that the forces of chemistry take possession, and the elements may explode, I had almost

said, with the facility of the fulminating compounds.

62, g. "There is," says Liebig, "in the nature and constitution of the (inanimate) compounds of nitrogen, a kind of tension of their component parts, and a strong disposition to yield to transformations, which effect spontaneously the transposition of their atoms on the instant that water or its elements are brought in contact with them." On the contrary, "it is found that no body destitute of nitrogen possesses, when pure, the property of decomposing spontaneously while in contact with water."—Liebig.

But, although dead animal compounds readily pass into sponta neous decomposition under slight degrees of moisture, yet, composed as they are, in part, of the elements of water, and very largely impregnated with aqueous substances in their living state, neither those elements, this water, nor any other agent, can disturb the exact combinations.

But, when the organic being dies, chemical agencies have their

play, and it is then that

"The result of the known transformations of substances containing nitrogen proves," according to Liebig, "that the water does not merely act as a medium in which motion is permitted to the elements in the act of transposition, but that its influence depends on chemical affinity. When the decomposition of such substances is effected with the assistance of water, the nitrogen is invariably liberated in the form of ammonia."—LIEBIG.

In respect to the inorganic world, had nitrogen been incorporated in its compounds, there would have been no stability among them. They would have been perpetually undergoing decomposition, until finally the whole of the nitrogen would fly off by itself, and nothing of the original compound would remain; and it could never be recombined.

62, h. Besides the disposition of nitrogen to tear asunder the ele-

^{*} Nitrogen is well known to abound in all the tissues of animals. Of vegetables, Liebig says, that, "Estimated by its proportional weight, nitrogen forms only a very small part of plants, but it is never entirely absent from any part of them. Even when it does not enter into the composition of a particular part or organ, it is always to be found in the fluids which pervade it."—Liebic's Organic Chemistry applied to Physiology, &c., p. 4.

ments with which it may be combined, the complexity of these elements in organic beings contributes to the disorganizing results after death, and is another principal cause of spontaneous fermentation and

putrefaction (§ 38, 41, 46, 48, 52, 53).

62, i. From the foregoing facts, especially from the universality and fixedness of nitrogen in organic beings, I arrive at the conclusion that the elements of their compounds are united by forces as peculiar as the facts which relate to these compounds, and that the forces of chemistry have no agency in combining the elements, or in effecting changes of their combinations during life. It is also abundantly manifest from my premises, that Liebig's declaration that "by chemical agency we can produce the constituents of muscular fibre, skin, and hair," is without the slightest foundation (§ 12, 13, 14).

62, k. The whole labyrinth of combinations in organic beings, and their ultimate return to binary compounds, are full of the most stupendous design. The final cause of the reduction of the organic being, when its own specific purposes are ended, is that of again supplying the means of growth to vegetables yet alive, that the elements may be again elaborated into ternary and quaternary compounds, to carry out the final purpose of the vegetable kingdom in supplying nutriment to

animals (§ 303).—Note C p. 1113.

63. In the Essay to which I have referred in the last section, I have endeavored to deduce the principles of vitalism from the phenomena that attend the development of the incubated egg, as had been briefly set forth in my "Examination of Reviews." The considerations there made are peculiarly appropriate to the present work, and to the place at which I have now arrived. It was my object to consider,

1st. The constitutional nature of the ovum.

2d. To show by the philosophy of generation, and by the nature of the powers which are universally admitted to be alone concerned in developing the germ or ovum, and in forming the organs of the new being, that the same powers are, also, alone concerned in carrying on forever afterward the processes of life, and, of course, that no new powers, or principles, are introduced.

3d. To consider the manner in which the germ is impregnated, or its vital properties so stimulated into action as to result in the development of the germ, and in unfolding the various attributes of the

new being.

4th. To show that we may find in the physiology of generation, or the principles through which the ovum is impregnated, the whole philosophy of organic life, or the principles through which the actions of life are forever carried on.

5th. To state the manner in which the natural peculiarities of each parent, whether as it respects the properties of life, or the physical conformation, are infused into the germ and combined in the full-grown offspring.

6th. To show that hereditary diseases are transmitted in the same way as those more natural peculiarities which belong to parents.

7th. To show, also, that the principles which are concerned in the transmission of hereditary diseases are the same as concur in the production of ordinary diseases.

8th. To deduce from the philosophy of generation the vital nature of hereditary diseases; or, in other words, to show that the morbid

impression is established upon the vital properties of the ovum, and of course, upon those of the new being; and that the hereditary vitiation does not consist in any transmitted impurity to the blood or other fluids of the offspring, as is now supposed by the humoralists.

If the foregoing propositions be true in relation to man, they will, of course, be equally so of animals, and of the whole vegetable king-

dom (§ 169 f, 1051, 1052).

64, a. If it be universally conceded, as a matter of course, that not only the elementary constitution of the ovum, but its whole development, depends entirely upon a vital principle or vital properties, it will follow that the same principle or properties are forever afterward concerned in organic processes, and alone concerned.

Let us hear, in the first place, the most eminent in the school of vitalism, but who are inclined to lean upon chemistry after the full

development of the ovum.

64, b. It is said, for example, by Tiedemann,

"That it is the vital power, which in the fecundated germinative liquid, brings the molecules of the organic combinations to the solid form, and calls the first lineaments of the vegetable and animal embryo into existence. All the parts and tissues that are formed in it, according to a definite order of succession, are products of the power of formation, and on this they depend in all that relates to their first appearance, their development, aggregation, configuration, and arrangement. The phenomena exhibited in the act of formation of an embryo, are placed far above all the mechanical and chemical acts we observe in bodies not endowed with life."—Tiedemann, Comparative Physiology.

64, c. By the illustrious Müller, it is said,

"The creative force exists already in the germ, and creates in it the essential parts of the future animal. The germ is potentially the whole animal. During the development of the germ, the essential parts which constitute the actual whole are produced." "The entire vital principle of the egg resides in the germinal disk alone; and since the external influences which act on the germs of the most different organic beings are the same, we must regard the simple germinal disk as the potential whole of the future animal, endowed with the essential and specific force or principle of the future being, and capable of increasing the very small amount of this specific force and matter which it already possesses, by the assimilation of new matter." And again he says, "This force exists before the harmonizing parts, which are, in fact, FORMED BY IT during the development of the embryo." "The vital force inherent in organic beings itself generates the essential organs which constitute the whole being " "The formative or organizing principle is a CREATIVE POW-ER, modifying matter blindly and unconsciously;" yet with such wonderful precision that Müller also says, that "this RATIONAL CREATIVE FORCE is exerted in every animal strictly in accordance with what the nature of each requires." "The vital principle," he says, "is in a quiescent state in the egg before incubation."—Müller, Elements of Physiology.

64, d. Passing from the chemico-physiological school to that of pure chemistry, we shall find the same admissions as to the exclusive agency of a vital principle in the formation and development of the

seed and ovum. The extraordinary contradictions, which will astonish the reader, necessarily abound in all authors who are employed in identifying two subjects that have no relation to each other.

64, e. Take Liebig, as a first example; and take, in the first place,

his chemical doctrine of life.

"In the animal body," he says, "we recognize, as the ultimate cause of all force, only one cause, the chemical action which the elements of the food and the oxygen of the air mutually exercise on each other. The only known ultimate cause of vital force, either in animals or in plants, is a CHEMICAL PROCESS. If this be prevented, the phenomena of life do not manifest themselves. If the chemical action be impeded, the vital phenomena must take new forms."

And yet only a few sections before, and in the very first sentence of Liebig's work on "Animal Chemistry applied to Physiology and

Pathology," we read,

"In the animal ovum, as well as in the seed of a plant, we recognize a certain remarkable force, the source of growth or increase in the mass, and of reproduction, or of supply of the matter consumed; a force in a state of rest.* By the action of external influences, by impregnation, by the presence of air and moisture, the condition of static equilibrium of this force is disturbed. Entering into a state of motion or activity, it exhibits itself in the production of a series of forms, &c. This force is called the vital force, vis vitae, or vitality."—Liebig's Animal Chemistry.

Turning back to the same author's work on "Organic Chemistry applied to Physiology," we meet not only with a similar contradiction of his grand doctrine of the entire dependence of life upon chemical processes (and as we had before seen in respect to digestion, section 60), but with that which is particularly apposite to my present inquiry.

"Our notion of life," says Liebig, "involves something more than mere reproduction, namely, the idea of an active power exercised by virtue of a definite form, and production and generation in a definite form (§ 59). The production of organs, the co-operation of a system of organs, and their power not only to produce their component parts from the food presented to them, but to generate themselves in their original form and with their properties, are characters belonging exclusively to organic life, and constitute a form of reproduction independent of chemical powers. The chemical forces are subject to the invisible cause by which this form is produced. This vital principle is only known to us through the peculiar form of its instruments; that is, through the organs in which it resides. Its laws must be investigated just as we investigate those of the other powers which effect motion and changes in matter."—Liebig's Organic Chemistry, &c., p. 355.

64, f. Roget, of high authority, maintains that,

"However the laws which regulate the vital phenomena may appear, on a superficial view, to differ from those by which the physical changes taking place in inorganic matter are governed, still there is really no essential difference between them." "It may, in like manner, be contended, that the affinities which hold together the elements of living bodies, and which govern the elaboration of organic products, ARE THE SAME with those which preside over inorganized compounds."

^{*} See my Examination of Reviews p. 7-28.

" Hence it becomes every day more and more probable that the forces immediately concerned in the production of chemical changes in the body ARE THE SAME as those which are in constant operation in the inorganic world; and that we are not warranted in the assertion that the operations of vital chemistry are directed by distinct laws, and are the results of new agencies."

"However natural it may be to conceive the existence of a single and presiding principle of vitality, we should recollect that this, in the present state of our knowledge, is only a fiction of the MIND, NOT WARRANTED BY THE PHENOMENA THEMSELVES."—ROGET'S Outlines

of Physiology.

Let us now hear this able writer on the subject of fætal development. "A portion of the VITAL POWER of the parent," he says, "is for this purpose employed to give origin and birth to the offspring. The utmost solicitude has been shown in every part of living nature to secure the perpetuity of the race, by the establishment of LAWS, of which the operation is certain in all contingent circumstances."

Roget ultimately describes, in his usual felicitous manner, the development of the ovum; and here we have nothing from our author

but the agency of the vital powers.

"The foundations of the edifice," he says, "are laid in the homogeneous jelly by the efforts of the vital powers." "At first, all the ENERGIES OF VITALITY are directed to the raising of the fabric, and to the extension of those organs, which are of greatest immediate utility; but still having a prospective view to farther and more important ends,"-and so on throughout the chapter; the whole work of developing and fashioning the fætal organs being assigned, exclusively, to "the efforts of the vital powers," and to the "energies of vitality."—Roger's Animal and Vegetable Physiology, Bridgewater Treatise.

64, g. Finally, let us hear, also, Dr. Carpenter, who advocates the chemical doctrines of life so far as to lay down the following principle no less than twice within six pages, and in nearly the same words. Thus:

"Reason," he says, "has been already given for the belief that the affinities which hold together the elementary particles of organized structures are not different from those concerned in the inorganic world; and it has been shown that the tendency to DECOMPOSITION AFTER DEATH BEARS A VERY CLOSE relation with THE ACTIVITY OF THE CHANGES WHICH TAKE PLACE IN THE PART DURING LIFE."-CARPEN-TER'S Principles of General and Comparative Physiology, p. 140; also, p. 146.

Now the authority of such a writer, and a prominent leader in the purely chemical school of physiology, must be allowed to be important when any unavoidable concession is made to vitalism. Let us

then hear him in the matter of the ovum:

"Organization, and vital properties," he says, " are simultaneously communicated to the germ by the structures of its parent. THOSE VITAL PROPERTIES CONFER upon it THE MEANS of itself assimilating, and thereby organizing and endowing with vitality the materials supplied by the inorganic world."-CARPENTER'S Principles, &c., p.

And again, this mere chemist, in his general views of the philosophy

of life, observes, that

"The agency of vitality, as Dr. Prout justly remarks, does not change the properties of the elements, but simply combines them [the elements] in modes which we cannot imitate."—Carpenter's

Principles, &c., p. 146.

64, k. Dr. Prichard is strictly of Dr. Carpenter's school (see my "Examination," &c., p. 37), between whom there is a point of agreement which is worth noticing in its connection with the subject now before us, and to which I have referred in a former work, in its relation to Dr. Carpenter. Both of these writers see so much of peculiar design in organic nature, and find it so impossible to interpret the phenomena of organic beings upon the chemical and physical principles which they have so strenuously set forth, and in their aversion to any other principles, and to the obvious rule of analogy as to second causes, that, in the end, they assign the functions and phenomena of life to the immediate action of the Deity.

"The theory of a vital principle," says Dr. Prichard, "has been applied in a different manner, to account for the phenomena displayed at the beginning of life in animals and vegetables, and to get rid of the mystery which attends the gradual evolution of organic structure from ova and germs. Here the vital principle is no longer considered a chemical agent, but assumes the character of a plastic and formative

power," &c.

Now Dr. Prichard "cuts the knot" and "gets rid of the mystery"

after the following manner:

"We may," he says, "if we choose to do so, term the cause which governs the organization and vital existence a plastic principle; but it is a principle endowed with intelligence and design [!] It is, in fact, nothing more than the Energy of the Deity." "The development of forms, according to their generic, specific, and individual diversities, not less in the vegetable than in the animal world, can only be accounted for by ascribing it to the universal energy and wisdom of the Creator."—Prichard's Review of the Doctrine of a Vital Principle. See, also, Paine's Commentaries, vol. i., p. 10, 25;

and his Examination of Reviews, p. 37, 41, 43, 44.

This is a far greater admission than the vitalist can desire; since, if the development and growth of the germ depend immediately upon Almighty Power, so must all the analogous processes of the living being at all stages of its existence, and science would be merged in the direct manifestations of that Power. But, while this doctrine is utterly exclusive of all the assumed chemical agencies at all periods of life, and overlooks the analogy between the development of the germ and the subsequent processes, there can be no hesitation as to the disposition which should be made of it, without any reference to its prevaricating nature (§ 175 d, 699 c, 740).

65. Having now before us a plain statement of our necessary premises as they respect the exclusive agency of the "vital principle," or "organic force," or "creative power," or "vital properties," or "vital powers," or "vitality" (whichever term may be preferred), in carrying out the full development of the embryo, it may be interesting to know the details of that development and growth, which is thus allowed, on all hands, to be conducted by powers utterly distinct from the chemical and physical, and in which these have no agency.

"The development of the separate parts," says Müller, "out of

the simple mass, is observable in the incubated egg. All the parts of the egg, except the germinal membrane, are destined for the nutrition of the germ. The simple germinal disk is the potential whole of the future animal, endowed with the essential and specific force. or principle of the future being, and this germ expands to form the germinal membrane, which grows so as to surround the yolk; and by transformation of this germ, the organs of the future animal are produced. The rudiments merely of the nervous and vascular systems. and of the intestinal canal, are first formed; and from these rudiments the details of the organization are afterward more fully developed; so that the first trace of the central parts of the nervous system must be regarded neither as brain nor as spinal marrow, but as still the potential whole of the central parts of the nervous system. In the same manner, the different parts of the heart are seen to be developed from a uniform tube; and the first trace of the intestinal tube is more than the mere intestinal tube; it is the potential whole, —the representative of the entire digestive apparatus; for, as Baer first discovered, liver, salivary glands, and pancreas, are, in the farther progress of the vegetative process, really developed from that which appears to be merely the rudiment of the intestinal canal. It can be no longer doubted that the germ is not the miniature of the future being, with all its organs, as Bonnet and Haller believed, but is merely potentially this being, with the SPECIFIC VITAL FORCE of which it is endowed, and which it becomes actually by development, and by the production of the organs essential to the active state of the actual being. A high magnifying power is not necessary to distinguish the first rudiments of the separate organs, which, from their first appearance, are distinct and very large, but simple. So that the later complicated state of a particular organ can be seen to arise by transformation from its simple rudiment. These remarks are now no longer mere opinions, but facts; and nothing is more distinct than the development of glands from the intestinal tube, and of the intestinal tube itself from a portion of the germinal membrane." -MÜLLER, *ibid* — (§ 1051, 1052).

Such, then, is the history of the development of the germ in birds, and in all the higher animals; and the whole work is ascribed by physiologists of every denomination exclusively to principles unknown in the inorganic world, and wholly distinct from any of a chemical nature. They are called, indiscriminately, vital properties, vital powers, vital principle, organic force, creative force, &c., to distinguish the principle, or properties, from every thing that has any known existence in inorganic substances, or as the source of any inorganic results. But, physiologists of the chemical school stop here, and ascribe all organic compounds after the being is fully formed to chemical agencies. It is remarkable, however, that it has not occurred to these philosophers, that precisely the same elementary combinations, the same formation into tissues, and the same secretions, take place at all stages of the rudimentary development as at all future periods of life, and that the rudimentary development consists in these formations of simple compounds and their union into tissues; and if the early or rudimentary growth of the being, all its secreted products, all its elementary combinations, be determined by the vital properties, so are the same results determined by the same properties

or powers forever afterward. To call in the agency of chemical or physical forces, to accomplish *precisely* the same results at any future stage of the organic being as are admitted to be performed in the development of the "essential parts" of that being by the "vital principle" or "vital properties" alone, is a violation not only of the plainest rule in philosophy, but of the clearest facts (§ 41, 42, 55–58).

66. We have thus before us a peculiar order of powers by which the organic being is developed, fashioned, and forever exclusively governed. It is these powers about which physiology, pathology, and therapeutics, are essentially concerned. We may, therefore, seek in the composition of organic beings, and in the laws of their development, for the great rudimentary principles of medicine. The vital principle has also the extraordinary task of laying out, in the ovum, the whole organization of the future being; so that its subsequent labor must be comparatively simple, and it is then, least of all, that it can require any help from the forces of the inorganic kingdom, or that it would permit a violation of the great principle in na-

ture of avoiding an unnecessary multiplication of causes.

67. It may be farther shown by the incipient development of the ovum, that the vital powers, or properties, are more concerned in the growth, nutrition, and all the subsequent physical results, throughout the whole existence of the being, than is generally supposed by even the exclusive vitalists. The usual supposition is that the vessels or instruments of action, which are moved by the vital powers, perform the work of decomposing the blood and other parts, and recombining them again in other proportions and forms, according to the particular organization of parts, and the modification of their vital states. It has been the doctrine of most physiologists till a recent day, that the ovum, in its germinating part, is a mere organic fluid, destitute of vessels, and all other parts of the future apparatus. Later researches, however, have disclosed the existence of a rudimentary cell; and it is said by Müller (1835) that "in the incubated egg the sole material for the first formation of blood is the substance of the germ or germinal membrane, which itself grows by assimilation of the fluid of the egg, or the yelk. It may be distinctly observed that the blood is generated in the germinal membrane before the vessels are formed;"* from which it appears that the first "assimilation of new matter" must take place without the agency of vessels, or of any parts which are subsequently formed; and, therefore, the same powers which enabled the cell to generate vessels, nerves, &c., continue to make the same conversion out of blood; and as all this was originally done without the aid of vessels, so must the same powers be forever operative with their subsidiary agency only. As the ovum possesses the potential whole, it is equivalent to the mature structure.

We see, therefore, that Müller, reasoning upon other grounds, may not have been altogether hypothetical in his inference that the "vital principle exerts its influence even beyond the surface of an organ, as shown by its effects on the chyle, in maintaining the fluidity of the blood," &c.

By the same rule, it may be at once shown that the only ingenious chemical hypothesis ever invented to interpret organic results,—the catalytic,—is purely an assumption; since this hypothesis is predica-

* Kölliker states that "the membrane of animal cells, the largest of which are velk cells, exhibit no structure of any kind."—Microscopical Anatomy, Wurzburg, 1852.

ted of the blood-vessels. But, if there be no vessels in the germ, the first vessels must, of course, be produced without the supposed chemical influence of vessels, and, by my showing, therefore, as to the subsequent formation of vessels and other parts, the supposed agency of the catalytic forces is a mere assumption (§ 41, 42, 1051; also, Medical and Physiological Commentaries, vol. i., p. 74-76).

On this subject, too, chemistry must abide by admissions which are made in the very face of consistency; so imperative is fact, and so imbecile is hypothesis. Thus, it is said by the distinguished chemico-

physiologist, Dr. Prout, that

"The most determined sceptic cannot assert that there is any necessary relation, or, indeed, ANY RELATION WHATEVER, between the mechanical arrangements and the chemical properties to which they administer. There is no REASON why the chemical changes of organization should result from the mechanical arrangements by which they are accomplished [!]; neither is there the SLIGHTEST REASON why the mechanical arrangements, in the formation of organized beings, should lead to the chemical changes of which they are the instruments" !- Dr. Prout's Bridgewater Treatise. - Such is the proof which chemistry offers.

68. The question then arises as to what is the particular office of those vessels where the elementary combinations and decompositions take place? Simply this: to convey, and eliminate through the agencies of the vital properties, those parts from the blood out of which the vital properties effect the new elementary combinations, whether solid or fluid,—to aid in arranging the new molecules, and to carry forward those fluid products which may be destined for other ends.

69. But, have not the nerves an indispensable agency in effecting the elementary combinations and decompositions? Certainly not, as I shall endeavor to show. But the sympathetic nerve exerts an influence upon all organic functions, and impresses a special condition upon all organic compounds, and this physiological law is extensively involved in pathology and therapeutics (§ 226, 232, 233, 399, 446 a,

461, $461\frac{1}{2}$, $488\frac{1}{2}$, 489, 512, 639, 746 c).
70. But, all the vessels, and all the solid parts of the organism, have their various specific offices. Here, in every part, reside the vital properties, which had been fully developed in the ovum, and here are they modified according to the exact nature of the organization and the peculiar final causes of "the properties of the vital principle" in each part. Hence they manifest peculiarities in parts that are apparently alike. The modifications vary, for instance, in the serous membranes, and more remarkably in the mucous, as known by the influence of foreign agents, their phenomena, their products, &c. The vital properties differ in different parts of one and the same continuous tissue, as in the mucous tissue of the nose, lungs, stomach, &c. Hence one of the important objects of studying the structure of organs, and the nature of their tissues; for, as the vital properties are naturally modified in different parts, so will their alterations in the same disease be different in different tissues of one organ, and, for the same reason, even of different parts of one continuous tissue.

These natural modifications of the vital properties in different parts have, at least, three great final causes. The first is what I have already stated, namely, to separate from the blood, through the agency of the capillary vessels, that exact part which is to be decompounded

at any given point; the second is, by these modifications, to enable "the properties of the vital principle" to decompound and recombine the elements according to the exact nature of the combinations which belong to the part; and the third, to qualify the properties, through the medium of the capillary vessels, to shape and unite the new molecules to the old. It is easy to apply this principle, under its different aspects, to all other vessels, as the veins, the secretory and excretory vessels of the glands, and the absorbents.

71. Now, at the first start of the development of the germ, "the properties of the vital principle" (as they are well designated by Müller) are but very imperfectly, if at all, aided by any of the foregoing physical means, though they come into operation at the moment they are successively produced. "The properties of the vital principle," therefore, must exist in that potential cell in a modification, and with a formative energy which they do not possess in any of the new developments; and herein it will have been seen that the very chemist

has come to this conclusion (§ 64 f, 190 b).

72. The process of generation presents a varied and most impressive illustration of the peculiarities of the vital properties, and of the manner in which they are liable to be impressed and permanently modified in their nature. It results in the production of organic beings similar to those which exercise the generative faculty. This faculty is therefore manifested with as many specific modifications as there are different species of organic beings. If we allow to the globe one million of distinct species of animals, the specific modifications of the germinal product will be as numerous, and these are more or less influenced by the semen of the male. The seminal or productive principle of the male exerts its special influences upon the living properties of the germ, and according to the special constitution of the ovum directs their operation in such a manner that none but beings of the same kind with the parents, where both are of the same species, are produced. That the various modifications which distinguish each species are determined by both parents is fully demonstrated in hybrid animals, and is sufficiently obvious in the transmission of the peculiarities of the male or female, where the individuals are of the same species. And, notwithstanding our supposed million of distinct species of animals, and the specific variations in all the parts of each species (§ 41), this almost endless variety is made up by successive depositions of elementary compounds out of mainly four simple substances (§ 37, 42, 46), three of which are gaseous, united in modes unknown to chemistry (38-40, 48), and which chemistry cannot detect, and forever uniting in different modes and proportions according to the exact nature of every part (§ 43, 44). The act of generation establishes the essential modifications which are to be continued, without variation, throughout the life of the new being; and this new individual, becoming in its turn the agent of procreation, perpetuates all the specific modifications which appertain to itself and to its ancestors. The intermingling of species, which results in hybrid animals, proceeds upon the same plan. It must therefore necessarily be, that the vital properties of the ovum are so impressed by the exciting influences of the semen that those peculiar elementary combinations and aggregations are started which ultimately make up the hybrid. "These vital properties," says Dr. Carpenter, "confer upon it the means of itself

assimilating, and thereby organizing, and endowing with vitality, the materials of the inorganic world;" leaving it, also, clear to all minds that the action of the semen must be exerted directly upon the vital

properties of the ovum (§ 189, 1051).

That this important question as to the direct action of the semen upon the vital properties of the ovum, and its capability of establishing certain modifications of these properties, and that the humoral interpretation of transmitted peculiarities is an unfounded assumption,

may be definitively settled, I will also add,

"The well-known fact, that when the Earl of Morton's Arabian mare was covered by the quagga, not only did the mule so begotten partake of the character of the sire, but when the mare was subsequently submitted to an Arabian stallion, by whom she had three foals at different times, the first two continued to exhibit some of the distinctive peculiarities of the quagga conjoined with the characters of the Arabian breed."—Montgomery, on the Signs and Symptoms of Pregnancy, p. 17. This should overthrow the whole fabric of humoralism.*

The author of the foregoing statement supposes that the semen "may influence several ova, and so continue to manifest its effect in the offspring of subsequent conceptions when impregnation has been effected" by males of another species. The reader will also not fail to remark that the history of this case is in direct conflict with the late attempts to revive the old doctrine of referring the germ to the male

parent (§ 67, 1051, 1052, 1078).

73, a. The semen, then, is a vital stimulus, and so far on a par with the ordinary stimuli of life. These may be natural, like air, food, heat, &c.; or they may be morbific, like malaria, poisons, &c.; or curative, like medicines. In all the cases, their action is upon the vital properties; and it is in consequence of these influences that the ovum is developed, that life is maintained, health preserved or impaired, or disease removed. The ova of oviparous animals show the analogy in respect to stimuli, and the principles involved, more impressively than those of viviparous; since by an admirable design, in respect to the former, the impression of the semen has a limited operation, when the vital properties of the ovum return to their quiescent state, but may be again roused into action by the simple stimulus of heat. (See Med.

and Phys. Comm., vol. i., p. 21, &c.)

73, b. The action of the semen upon the properties of the vital principle of the germ is a type of all the influences that are produced upon the same vital properties during the life of the animal, and from which all its organic actions, and all their results, arise. And so of the germination and growth of plants; which, by-the-way, evinces the common nature of the principle of life, and of organic actions, in the two departments of the animated kingdom (§ 188½, d). It is the whole essential philosophy of physiology. It is the alterations produced in the vital properties which constitutes the philosophy of disease, and in which, indeed, all disease virtually consists. It is the art of finding out the remote causes, and the nature of the alterations they produce, and of adapting to the altered condition of the properties of life such agents as shall establish new impressions upon them, and thus enable them to return to their natural state, which forms the basis of therapeutics in its connection with pathology.

74. a. Here I shall digress for a moment, to consider certain anal-

^{*} The same is stated of Sir \bar{G} . Ousley's mare and a zebra, and of a mare and an ass, and the subsequent foals by stallions.

ogies in the development of special organs, through the influence of specific stimuli, with that general evolution of the organic fabric which is started by the action of the seminal principle upon the germ. These analogies are to be found in the organs of animal life. The senses, for example, sometimes manifestly require for their full development the prolonged operation of the stimuli which are natural to each. This is habitually observed in the young of some animals, and is seen conspicuously in the subterranean fish of Kentucky. In this last instance organic life is perfectly developed; but, owing to the exclusion of the natural stimulus of the eye from the very outsets of life, that organ remains in its rudimentary state.

A fortiori, therefore, the reputedly first inhabitants of this globe, such as the trilobite, attest the existence of the same light at their creation as is enjoyed at the present day; geologists to the contrary not-

withstanding (\S 1079, b).

Superficial observers of nature, either through inattention to the moral consequences, or through infidelity, are apt to believe that physical agents are the real creative forces of organic beings, from observing that particular parts are clearly dependent for their development upon the action of certain specific stimuli. But, in all these cases, the rudiment is there, and has been perpetuated ever since the original species came from the Hand of Creative Power. That Power is entitled to all the praise, as the Author of the rudiment, of its endowment with peculiarly modified properties of life, of the existence of the physical agents, and of the mutual adaptation of these modified properties of the rudiment and the virtues of the physical causes, so that the operation of the latter upon the former shall result, for example, in vision, and, under certain circumstances, as when the ovum is developed and matured out of the body, the physical agent, in the example supposed, shall be necessary to the development of the rudimentary organ of sight (§ $350\frac{3}{4}$, $h-350\frac{3}{4}$, l). The principle is much the same as that which applies to the necessity of external heat and light to the development and growth of plants. The specific stimulus of light by which the vital properties and actions of the leaf are enabled to decompound carbonic acid, and to assimilate the carbon, is manifestly a parallel example with my supposed influence of light in developing an animal organ in which the nervous system is extensively incorporated for the final cause of the whole organ; although it be certainly true that, in the case of the eye as of the leaf, the essential influences of light are exerted upon the organic properties of either part, and that the nervous system, in the former case, is only a medium of transmitted influences to the organic properties (§ 188, 1881, 189, 202, 203, 222, 223, 226, 227, 514 k, 1072 a, note).

It would be an interesting inquiry to ascertain whether, by a total exclusion of light from the ovum of fish, after fecundation, the peculiarity of the Kentucky wonder may not be established in the first generation; and whether, also, an exclusion of light for a series of years would not be followed by a failure of the balance of absorption and nutrition in the eyes, and consequently a wasting of those organs. The general law of absorption operates universally, without the aid of any specific stimulus; while it is clearly otherwise in respect to nutrition, and especially in regard to certain organs. The voluntary muscles become emaciated from want of the stimulus of exercise, &c

We see, therefore, how it happens that fishes with and without eyes may exist together in subterranean caverns as extensive as that of Kentucky; the latter inhabiting the dark regions, while the former exist in springs near the crevices of the cave (§ 136, 137, 548 a, 649 d, 733 b).

74, b. Such, then, is my philosophy of this subject, and such the full extent of the ground upon which infidelity would plant its standard. Nor will I dismiss this subject without referring, now and hereafter, to the calm indifference with which this infidelity is regarded even by the religious world, by adducing not a few of the present popular

treatises on theoretical geology (§ 3503, g-k, 1085).

75. Let us now see if the beginning of individual existence does not supply a key to the whole philosophy of disease, as it does to that of physiology. We have seen that all the actions, and all the results of life, are merely effects which arise from the operation of the vital properties through their organic instruments (§ 65-67, 133, &c., 188, &c.). These properties must be constantly excited into action by foreign agents, as by food, blood, &c., or the properties will become extinct, and, of course, the effects will cease (§ $188\frac{1}{2}$, b). Now, the actions in disease are nothing more than the altered actions of health, and the same rule applies to all the morbid products. It follows, therefore, that the properties of life, upon which these altered conditions depend, are modified or altered in a corresponding manner. As a consequence of this, it also results that the vital properties have been varied from their natural state by agents or causes capable of producing the change. These agents make their impressions in the same way as the natural stimuli of life, only the morbific agents at the same time affect the nature of the vital properties, and bring them into a new condition. This new condition constitutes disease.

76. The type of all this may be found in the impregnated ovum. The properties which animate the germ before conception are determined entirely by the vital constitution of the female parent. But we have seen that the new being may partake of the physical characters of the male as well as of the female, and it happens not unfrequently that the characteristics of the male are predominant. Hence it follows that the semen so far establishes changes in the original consti-

tution of the vital properties of the germ.

Since, therefore, all the fætal developments, all their physical peculiarities, depend upon the precise modifications and actions of the vital properties (§ 70), and since these properties in the unimpregnated ovum are determined entirely by the female parent, their nature after impregnation must be more or less affected, and assimilated to the peculiar nature of the male parent in all the cases where the offspring manifest any of the male characteristics. This is entirely analogous, in principle, to the modifications which are produced in the properties of life by morbific causes; but with this difference in contingencies: in the case of the impregnated ovum the modifications are permanently established, and can never be altered, so far as the vital properties, in either parent, upon which the modifications depend, are fundamental in their nature. In the case of the morbific agent, or the cause of disease, the vital properties are diverted from the healthy state, and from such modified conditions they commonly possess the ability of escape, and of returning again to their natural standard (§

853, 858, 898). In the case of the impregnated ovam a modifying agent operates, whose properties are intended to confer on the new being a stable condition, however they may modify the exact constitution of the impregnated germ. This vital stimulus, the semen, therefore, in virtue of its specific properties, bestows upon the corresponding vital properties of the ovum the peculiarities which belong to itself; and these being natural, vital, and determinate, the transmitted peculiarities should be equally so. Or, where the male parent enjoys a perfectly natural constitution, the innate predispositions to disease depend upon special peculiarities in the vital state of the ovum, which may be as permanently established, through the modified constitution of the female parent, as any of the natural characteristics. In the case of disease, however, the morbific agents have none of the properties of life which are natural to the fecundating semen, and the modifications, therefore, which they may determine may be different, even if we suppose them to act, as in the case of the germ, upon the whole constitution. Whatever modifications, therefore, may arise from their action, they must consist of deviations from the standard of health. But, it does not necessarily follow that certain artificial modifications may not be as permanent as the natural ones; and it is from observation alone, that we learn that they are so, or nearly so; as in the case of artificial "temperaments," the effects of domestication upon animals, the changes which are wrought in the vegetable kingdom by cultivation and by change of climate (§ 535, &c.).

77. In the case, however, of the formation of temperaments by change of climate, and the more remarkable alterations produced in animals by domestication, and in plants by cultivation, &c., the results are brought about by the new and habitual influences to which the properties of life are exposed; and, in all these cases, a radical, and often permanent modification is established, approximating closely the modifications which are bestowed upon the germ by the fecundating semen. Now, it is also true, that what is denominated predisposition to disease is entirely analogous, in principle, to the permanent temperaments of which I have just spoken. Both are results of physical agents, modifying the properties of life; and this chain of analogies conducts us to those predispositions to disease which are impressed upon the germ by the fecundating semen, and by which I show that the philosophy of the operation of morfibic causes is variously, and even exactly exhibited in the impregnation of the germ (§

63, 75, 535, 539, 559).

78. Take the scrofulous subject as supplying an example of hereditary predisposition to disease. If it exist in the female, her ova will partake of this peculiar modification of the vital properties, and it is in this way that her progeny inherits the scrofulous diathesis (§ 144–147). In this case, as in all transmitted predispositions to disease, the peculiarities induced in the parent bave arisen, originally, from the operation of deleterious agents—imbuing the ovum with the modifications belonging to the female, or imparting to the semen the whole concentrated force of what may have been the slow work of numerous causes upon the male parent.

Here, then, we see illustrated in the very ovum, even before impregnation, the whole principle which concerns artificial temperaments, and those influences of morbific agents which establish predis-

positions to disease in the full-grown subject. It frequently happens also, that this natural diathesis is so great, that it results in actual disease before the birth of the offspring, as manifested by tuberculous

affections of the lungs in still-born infants.

79. But, to make the philosophy of this subject more obvious, let us consider the germ when it derives its scrofulous diathesis from the male parent. Before impregnation its vital condition is perfectly natural. The semen of the male parent establishes upon it the modification which constitutes the predisposition to scrofula, just as malaria determine those modifications which result in fever, &c. And here we may readily detect a perfect analogy between the alterative influences of the semen and of remedial agents, and come to understand how it is that the latter produce their effects (§ 904, d). We have only to observe those instances where some of the offspring inherit the scrofulous diathesis of the female parent, while others are as entirely exempt as the male parent; the natural condition of the semen having altered the vital constitution of the ovum in the latter case, and impressed a disposition to a development of the new being in its perfect state.

80. The subject may be pursued under a variety of aspects, and with various illustrations, whether physiologically or pathologically. Other exemplifications will occur under the subjects of vital habit and the temperaments. The same principle is concerned throughout, whether in respect to the physiological conditions impressed upon the ovum by the seminal fluid, or as those conditions are modified in hereditary scrofula, gout, &c., or whether it concern the temperaments and other permanent changes that are induced by climate, domestication, &c., or as malaria may establish their peculiar modifications of the properties of life. Nor can such conclusions be unexpected to those who duly consider the simplicity of nature in her elementary

principles and laws (§ 561).

81. Could the doctrine entertained by Walker, Elliotson, and others, that the imagination of the parents influences the physical organization of the offspring, be shown, the philosophy which I have set forth, though not rendered more clear, would be yet fortified. But, this is at best but speculation. I could, however, turn to the mysterious production of the soul. This remarkable principle is doubtless developed at the very outset of fætal life, as evinced by its often combining the intellectual peculiarities of both parents, or, again, of manifesting chiefly those of the male. But here we have no other fact to guide us, and all beyond has been involved in an impenetrable mystery by the great Creator. Here it is a pride and a help of philosophy to rest on faith alone (§ 433).

82. For an examination of vital phenomena, and relative facts, in proof of the existence of properties peculiar to organic beings, and of the abstraction of such beings from the laws of the inorganic world, see Essay on the "Vital Pewers," in Medical and Physiological Com-

mentaries, vol. i.

SECOND DIVISION OF PHYSIOLOGY.

STRUCTURE.

83, a. There are certain details in respect to the structure of organs which must be stated, now and hereafter, to enable us to comprehend the laws which govern the healthy and morbid states of man

Perhaps few things can impress us more forcibly with the importance of a correct analysis not only of the physical organization of all parts of the body, but more especially of the vital characteristics of each part, than the continued propagation from high sources of doctrines like the following; while they equally prove my position as to the appropriate sources of knowledge ($\S 5\frac{1}{4}-5\frac{1}{2}$, &c.), and the tendencies of the microscope.*

83, b. The errors in doctrine to which I have referred are revealed sufficiently in the following extract from an article by the distinguish ed Mr. Paget, contained in the 27th volume of the Transactions of the Royal Medical and Chirurgical Society, London, 1844. The article is entitled "An Account of the Examination of a Cyst containing Seminal Fluid;" in the course of which Mr. Paget observes,

"If, with the aid of these observations, we endeavor to find an explanation of the occurrence of spermatozoa in the fluid of cysts connected with the testicle, we may suppose either that the fluid part of the semen has permeated from the seminal tubes into the cysts, and been farther organized in them; or, that the cyst itself secretes a fluid in which the organic structures of the semen may be developed." "The most probable explanation of these cases, therefore, seems to be, that certain cysts, seated near the organ which naturally secretes the materials for semen, may possess a power of secreting a similar fluid"† (§ 251).

I cannot doubt that before I shall have parted with the reader in what I shall have said of the peculiarities of structure, and the more remarkable modifications of vital properties and functions, there will be a disposition to concede the importance of the subject, and that this importance is rendered more manifest by the prevalence of opinions analogous to those in the foregoing extract.

83, c. As I have already intimated, however (§ 2, c), anatomical science can lead, originally, to no conceptions of the properties and function of life, and therefore to none of their modifications in dis The most that we can infer, abstractedly, from a knowledge of structure, are certain general results that are denoted by the constitution of organs, or assemblages of organs, upon the known principles

^{*} See Medical and Physiological Commentaries, vol. i., p. 699-712. Also, my Exam-

^{*} See Medical and Physiological Commentaries, vol. i., p. 699-712. Also, my Examination of Reviews, p. 6, 89, 90.

† The Medico-Chirurgical Review for January, 1845, quotes this paragraph, and observes of it, that "Mr. Paget's explanation of the vicarious appearance of the spermatozoa, which has of late so much puzzled the members of the society, has the merit of being ingenious and original."—I cannot acquiesce in this decision. The doctrine is old, though recently, for the first time, enforced by the deceptive report of the microscope. It is thus noticed in the Medical and Physiological Commentaries: "True, we know that the ancient belief is even maintained at this day, by Sir A. Cooper, and others, that the testis is of no special use, but that the semen is the product of those simple reservoirs, the vesiculæ seminales. But, what does this show?" &c. See, also, my comments on this subject, in vol. i., p. 588, and on the supposed vicarious secretion of milk, urine, &c., p. 601-603.

of Design. The construction of the eye, for example, evinces some great final cause relative to light; that of the urinary apparatus, that a fluid is produced by the kidneys, and conveyed to a receptacle where it accumulates, and is finally evacuated through the urethra; and so of many other parts. We thus infer, also, the uses of each part, individually, from their relations to each other as a system of Design. In other cases the function of a part may be inferred from the known uses of other parts to which it is related; as the valves of the veins, for example, were supposed by Harvey to be designed for giving the blood a direction toward the right cavities of the heart; and this induction from anatomical Design conducted him to a full exposition of the circulation. But, in respect to the great processes of life, no conclusions can be originally drawn but through their phenomena, nor does structure denote even the principle of vision (§ 251).

Having, however, acquired a knowledge of structure in a particular species of animal, as man, for example, and learned the uses of each particular part by a study of its phenomena, so perfect is the system of Design throughout organic nature, and so harmonious are the analogies of function among organs that bear certain resemblances of structure, or of relations to each other, in all species of animals, although the differences in respect to structure, particularly, may be very great (§ 107, 409, e), yet illustrated by greater analogies of relation, we may generally infer, by this analogical process ($\S 5\frac{1}{4}$), the absolute uses of every part in any species of animal that may be, for the first time, subjected to the knife of the anatomist. And this process of induction may be carried to a great extent from an established standard of comparison in the animal to the vegetable kingdom. But the principle is equally comprehensive in respect to plants, when, as with animals, a complex being is marked out, as a standard, in all its struccures and functions.

The same is also true, though in a far more limited extent, of the modifications of structure, and the corresponding modifications of function, at the different eras of life (§ 153–162). And when we come to the variations of function in morbid states, though unattended by any appreciable alteration of structure, and consider how various must be the treatment according to the nature of the affected tissue, we are deeply impressed with the indispensable importance, to the physician, of an accurate knowledge of all that is relative to the sensible organization of the material part of organic life (§ 2, c). Though the structure, itself, reflect no light upon pathology, excepting through its morbid alterations, an observation of its morbid phenomena leads us to a knowledge of the parts diseased, and this knowledge is important to a just interpretation of the phenomena, and to a right method of treatment (§ 131).

832. We have now seen that the composition of organic beings is formed by properties peculiar to organic structure, and that what is thus at the foundation presides over all, and is the cause of all that is superinduced upon that composition. The structure of organic beings, which is comprehended under our second division of physiology, is therefore dependent on the same creative cause.

84. The greatest physical characteristic of organized structure is supposed to be its arrangement into cells. Here all analogy with inorganic substances disappears entirely. The chemico-physiologists

imagine that the contradistinction between organic and inorganic beings commences at this step in the ascending series of organic results (§ 42). But we have seen sufficiently that all that relates to the composition of plants and animals is equally significant of a radical distinction between the simplest organic compound and those of an inorganic nature; the same powers being equally concerned in the formation of organic compounds as in their arrangement into tissues.

85. The general structure of organic beings is made up of tissues. A knowledge of the vital characteristics of the different compound tissues, of the same tissue in separate parts, of the different parts of one and the same continuous tissue as it may pass through different compound organs, of the whole as they may be combined into complex organs, of their vital relations to each other, and of all parts to each other, is indispensable to a knowledge of the laws in physiology, pathology, and therapeutics.

86. Bichat analyzed the tissues more ably than others, and arranged

them as follows:

1. Cellular. (cerebro-spinal. 2. Nervous ganglionic. { involuntary. voluntary. involuntary. 3. Muscular 4. Vascular venous. (lymphatic. 5. Osseous. (fibrous. fibro-cartilaginous. 6. Fibrous dermoid. 7. Erectile. 8. Mucous.

Glandular.
 Epidermous, or corneous.

87. Until the era of Bichat, the tissues were limited to three, as designated by Haller; namely, the cellular, muscular, and nervous. The cellular was supposed to form a large proportion of other tissues.

88. There was a great error, physiological and pathological, in the foregoing limitation (§ 87), since it took no note of the modifications of the vital properties, and of the particular functions of the tissues as

arranged by Bichat.*

9. Serous. 10. Synovial.

89. The several tissues are distinguished by differences of internal structure, as well as by modifications of their properties and functions. They are called simple organs, when considered in their functional character; and when two or more go to the formation of more complex parts, they are called compound organs. Certain compound organs, which concur together in some general function, are called an apparatus; as the urinary, the digestive, the circulatory, &c. As the whole exist in the universal body, they are called an organism. Each tissue, collectively, is also a system; as the mucous, serous, muscular, &c

^{*} For practical purposes Bichat's analysis has not been improved, nor probably can be-1860.

91. The simple tissues rarely occur in a separate state, but are

more or less connected together into complex organs.

92. The simple textures are, themselves, compound organs, so far as their organization is made up of various tissues. The union of tissues, therefore, in the simple textures, is quite different and far more intricate than when the simple textures form what is called, specifically, a compound organ.

93. The structure of the general body, and of its different parts, is radiated. The rays, or branches, of certain parts, as the vessels and nerves, are called ramifications. The rays increase in number and

diminish in size, as they go off from the centres of radiation.

94. The trunks of vessels and nerves, and their ramifications, unite, respectively, in various ways with each other. This is anastomosis, and subserves very important uses. It promotes circulation in the vessels, and through the nerves it contributes especially to bind all the organs together in one harmonious action and common dependence. Through the last, also, the play of reflex nervous actions is promoted when the nervous power is developed in the central parts of the cerebro-spinal and ganglionic systems by morbific or remedial agents.

95. The animal organism is symmetrical as a whole, and in its various parts. This symmetry is conducive to uniform results, is important to the great processes of life, is always the same in the natural conformation, is indicative of great Design, and of peculiar proper-

ties and laws.

96. Bichat, "following the path marked out by nature herself," divided the animal organism into two great systems or classes; the distinction having been already indicated by Aristotle.

97. The first class relates to the individual being; the second to

the species.

98. The first class is divided by Bichat into the organs and functions of animal life, and the organs and functions of organic life.

99. "The two classes have nothing in common, but the general connection that unites all the phenomena of living bodies; but a variety of distinctive attributes characterize them, which cannot be separated from them."—BICHAT.

100. The organs of animal life are those whose functions connect us sensibly with external objects, are peculiar to animals, and distin-

guish them from vegetables.

101. The organs of organic life consist of such as perform functions that are common to animals and plants. "The only condition of enjoying this life is organization." It forms an indisputable boundary between organic and inorganic bodies.

102. Animals have two states of existence, sleeping and waking; but the former applies only to the division which embraces the functions of animal life. The animal powers are subject to fatigue, and require repose; the organic are not, and are in perpetual operation.

103. The fœtus has only the organic functions in operation; but all its animal faculties and the soul exist in a passive state.* The latter

are brought only gradually into exercise.

104. The great, immediate, office of the organs of organic life is to maintain a constant vital composition and vital decomposition of organic matter; or nutrition and waste.

^{*} See Medical and Physiological Commentaries, vol. i., p. 13.

105. The organs of digestion, absorption, circulation, respiration, and secretion, compose organic life. Secretion comprehends nutrition, exhalation, calorification, and excretion; which four are often ranked as distinct functions.

106. "Animal life is composed of the organs of sense which receive impressions, of the brain which perceives them, reflects, and wills, of the voluntary muscles, and larynx, that execute this volition, and of

the nerves which are the organs of transmission."—BICHAT.

107. The organs of organic life are quite analogous in the lowest animals and plants; but each has peculiar characteristics. In animals a little higher in the scale, the common functions are performed by organs of greater complexity, and this complexity increases in the ratio of the development of animal life. Nevertheless, in most animals above the rudimentary there are the same subsidiary functions, whatever the difference in organization. There is in most, for example, the secretion of gastric juice, saliva, bile, &c., which subserve the common function of assimilation.

108. No organ of animal life, in a philosophical sense, is necessary to the individual. But, no part of the animal can exist without all parts of the organic system, or an equivalent; which is also true of the organic viscera. If the heart, for example, be wanting in the fœtus,

the blood-vessels, as an equivalent, carry on the circulation.

109, a. The indispensable organs, of which no one can be abstracted without destroying the whole, are generally single in animals (§ 128). The same is true of plants, if we regard those organs which perform a common function in the light of a single organ. If the leaves fall spontaneously and abruptly in cold climates, no injury results to the

plant, because it is passing into a torpid state.

109, b. Nevertheless, neither the action of the heart by which the blood is circulated, nor that of the lungs by which the blood is oxygenized, nor that of the brain by which the harmony of organs is maintained, nor that of the kidneys and skin by which redundancies are excreted, nor that of the liver by which bile is generated, nor that of any other compound organ, constitutes the real functions of life. They are only secondary or subordinate to others in which the absolute processes of life consist; and these are carried on by those extreme vessels which perform the immediate work of nutrition and vital decomposition. This is exemplified in the development of the ovum (§ 63–72), and throughout the vegetable kingdom. Indeed, life may be continued after removal of the brain merely by inflating the lungs; and could we substitute a machine for the heart, and the process of transfusion, both the heart and the lungs could be dispensed with for awhile.

These facts are important in showing the nature of the organic properties; how it is, and through what influences, the compound organs contribute, and are, each one, indispensable, to the life of animals; and that it is to the fundamental organization that we must look for all the absolute processes of life, and for the essential conditions of

disease (§ 1041).

110. The parts by which life is carried on in the organic viscera are blended in the organs of animal life, and in those of the species.

111. The cerebro-spinal system is assigned both to animal and organic life. The sympathetic, like the cerebro-spinal, goes to the organic life of animals, and therefore pervades the organization in animal as in organic life (§ 110).

The cerebro-spinal nerves and the sympathetic interchange contributions, in all parts, by which important influences of the former are established in the organs of organic life (§ 452, &c., 500, 512, $514\frac{1}{2}$ -530, 889, $891\frac{1}{2}$, g, k, 893, a, c-e, 902-905, 940-952).

112. Nevertheless, the cerebro-spinal system is especially designed for the uses of animal life; but an important final cause is answered in making it subservient to the common interests of the whole being

(§ 455).

113. The sympathetic system is added especially to the organic life of animals on account of the complexity of the organs, and to unite them in harmonious action, through circles of sympathy, and thus render them, each in its place, conducive to a common end. The cerebro-spinal system contributes to this result (§ 111, 112); and each system, unitedly, or independently, exerts special influences on the specific actions of organs, though these actions are carried on essentially through properties inherent in the several tissues (§ 226-233, 485). The nervous influence thus also bestows upon animal compounds peculiarities that do not obtain in plants (§ 461, 489, 493 cc).

114. The most important common end (§ 113), as it respects the individual, relates to the functions of animal life. The organic system, then, in animals, though physiologically the most important, must be held subordinate to the uses of animal life. In plants, organic life is

the whole being.

115. The foregoing union of organic life with all other parts (§ 110-114) establishes mutual relations between all parts of the organism, and brings the animal and sexual systems under the laws which appertain to the organic system (§ 455).

116. The same intimacy of parts confounds, in a degree, the distinction in the two lives (§ 115).

117. An important consequence of the foregoing vital union of organic with animal life (§ 110-114) is a general coincidence in the pathological as well as physiological condition of the whole. The diseases of each react mutually on each system of organs, each requires common methods of treatment, and remedial, as well as morbific, agents operate upon the universal body through any given organ (§ 455, 524, no. 1, 647), by exciting reflex nervous influences.

Nevertheless, diseases of the animal organs more readily derange the organic viscera than the latter the former; but, remedial agents operate far more powerfully in the opposite relation. The sympa-

thies in the two lives, therefore, are not exactly reciprocal.

The foregoing apparent want of harmony in the physiological, pathological, and therapeutical relations of the two systems of life is reconciled by the consideration that nature has ordained, for the protection of the organs of animal life, that their wants shall be emphatically made known to those of the life on which they depend, and, on the other hand, their dependence on organic life has placed them under the special therapeutical control of that life; while the organic viscera being independent of the organs of animal life, therapeutical influences are but feebly propagated from the latter to the former. Such are the final causes in the great plan of Unity of Design.

118. The second class of organs and functions, which relate to the species, are divided into three orders: 1st, such as belong to the male;

2d, to the female; 3d, the functions relative to impregnation.

119. The several organs, and reproduction, belong both to plants

and animals. They are not necessary to the individual, though the

whole organic system is necessary to their existence.

120. Although the organs of generation be not necessary to the individual, they exert many natural vital influences upon the animal functions. Their full development has also certain influences in organic life, which illustrate some important laws as to the vital properties. Their diseases may also give rise to great derangements of the organic functions. They fail earlier than the animal functions (§ 117, 578).

121. In the great sense of ultimate Design, all organic processes have for their final cause the development of the generative organs, and the production of germs; that similar beings may be maintained in one unvarying round of development and growth. Many beings die as soon as this end is attained, and return to the mineral kingdom to be again reorganized by plants, and again, and again, refitted for the nutriment of animals, and carry out, in both organic kingdoms,

the final cause of their regeneration from the mineral.

122. It is necessary that the ovum of mammiferous animals should remain connected with the parent till the organs of organic life are developed. The law of dismemberment (§ 108, 109) does not apply to the ovum of oviparous animals, nor to the seed. They are endowed with the whole essential organization, and maturity of the vital principle, for independent life. The former gets its nutriment from the parent, till the organs are brought forth. The latter are supplied with nutriment from within themselves. In this case, also, the species are destined for great multiplication and distribution; in the other, their numbers and sphere are more circumscribed.

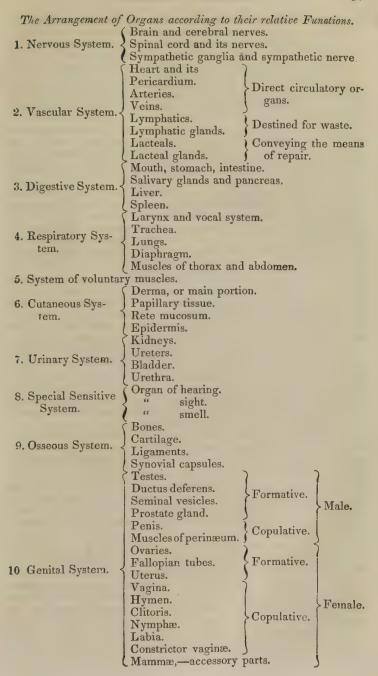

Nevertheless, the germ of all animals contains within itself the principle of carrying out the full development of a being similar to the parent, in all its complicated parts, which, however, have no rudimentary existence in the ovum. The progress, too, of fœtal development is always the same in each species, and every part is brought forward in the order of its importance in the organic life of the fœtus, and of its future uses. It is the same in the vegetable kingdom.

123. The history of the seed and egg probably supplies one of the most remarkable illustrations of Design that can be found in nature; especially that of the seed. They are the only instances where the entire properties of life cease their ordinary operation without be coming extinct; and were it not for this interval of repose, the species would probably disappear; since, even if the properties of life carried out the development of the seed into the plant, the chances of preservation, and especially of multiplication, would be vastly diminished (§ 633, 1051, 1052).

124. Besides the foregoing general division of the organs and functions of living beings, another arrangement of the organs is founded upon the relation of special functions. Each component part, each group of organs, and the whole collectively, are replete with various and wonderful Design; each, and all, having peculiar ends, all conspiring to common ends, and in one harmonious Unity of Design

maintaining the life of each other.

125 The following is

126. The organic and animal functions are also naturally subdivided into,

1st. Those which operate from without inward, as in digestion; and, 2d. Those which operate from within outward, as in circulation, secretion, &c.

127. There are generally two sets of organs for the animal functions, having a harmony of action in their natural and healthy states.

128. When the organs of organic life are in pairs, as the kidneys, concerted action is not necessary; and here one organ may supply the place of both (§ 109).

129, a. The whole assemblage of organic viscera act together in concert; but the animal organs, as a general system, act more or less

independently of each other.

129, b. The mutual relations which subsist between the various organs and their several functions are of two principal kinds; namely,

the vital, and the mechanical.

129, c. The first class of relations may be distributed into three different orders. The first order consists of the relations between the organs of sense. The second order embraces those between the brain and voluntary muscles. The third order comprises the relations which are especially maintained by sympathy. It is the last subdivision, mostly, which is relative to our present subject. It concerns, therefore, the organization by which organic life is carried on in animals, and depends upon the nervous power in its function of sympathy, and upon a principle independent of the nervous power, called continuous sympathy, and which is probably also an important principle in plants (§ 111-113, 222, 233, 495-500, 638½, 818½).—Note U.

129, d. The vital relations of a general nature evince the highest order of Design. They refer to the mutual co-operation of distinct systems of organs in the production of particular results, and of these various systems in the maintenance of universal life; while the several individual organs possess distinct and specific offices that are more or less dependent upon the principle of sympathy (§ 222–233,

455), that is, reflex action of the nervous system.

129, c. The sympathetic relations are most strongly pronounced among organs which concur together in the performance of special functions, as the circulatory, the digestive, the urinary, the sexual systems, &c. (§ 124). Other special relations subsist between the brain and the organs of animal life through the medium, in part, of the mental functions. Such is seen between the brain and voluntary muscles in the production of voluntary motion (§ 500, d). Thus, also, the senses aid each other; the sight being most independent. In this way, too, a concurrence is established between the teeth, muscles, eyes, nose, &c., in procuring food and supplying the stomach; each individual part having been also constituted with a reference to the nature of the food, and the mode of obtaining it (§ 323).

129, f. Plants are devoid of all that intimate association of parts which is owing to reflex nervous influence in animals, as well as to peculiarities of structure and special modifications of the common properties of life. But, a general relation of functions obtains to a certain extent in plants through the law of continuous sympathy, which, as I have en leavored to show, depends upon the organic properties

and which I would designate as continuous influence (§ 498).

129, g. The sympathetic relations in organic life are of the very highest moment in medicine. Disease is propagated, is maintained.

and removed, very greatly, through these natural relations.

129, h. The sympathetic relations are variously modified by disease, and are often more strongly pronounced than in health, though more or less diverted from their natural condition. Remedies also operate with greater effect through these modified relations, as well as through the greater susceptibility of the organic properties (§ 137, d). For the same reason, natural stimuli, as food, often prove morbific in diseased conditions (§ 152, b). The sympathies which grow out of morbific agents depend upon the natural principle, of which they are only modifications. And so of those which spring from remedial agents; these agents giving rise to greater influences in consequence of the morbid state of sympathy and of the organic properties, as well as in consequence of their own intrinsic virtues (§ 718, 901).

129, i. It appears, therefore, to be a most important law, that morbid states call into operation reflex nervous actions among organs, which, in their natural state, manifest but feeble, and perhaps no direct relations whatever; and that, in consequence of morbid changes, remedial agents will operate sympathetically through the stomach, &c., upon remote parts, when they would have no such effect in the healthy state of the organs. This principle is demonstrated in every case of disease, and constitutes our first position against the humoral pathology, and the doctrine of the operation of remedial agents by absorption (§ 819, &c.). New vital relations being developed by disease, our remedies continue to operate through those acquired relations so long as they exist; while, also, the remedies themselves may institute analogous sympathetic relations, and thus simultaneously induce reflex nervous actions of a salubrious nature in organs not morbidly affected (§ 74, 117, 137, 143, 155, 156, 387, 422, 514 h, 524 d, 525, 528, 733 b, 905, 980).

129, k. The mechanical relations are equally common to plants and animals. They are maintained by the motion of matter from one organ, or part, to another; as the transmission of blood from the heart through the blood-vessels, sap from the roots to the leaves of plants, food through the intestinal canal, urine from the kidneys to the bladder, and from the bladder through the urethra, &c. But, the movement of the matter is effected by the vital properties operating through

the various organs.

130. Every part is a perfect labyrinth, anatomically considered. It is a labyrinth, also, of perfect designs; while the harmonious concurrence of these designs in the aggregate organs and tissues is too profoundly complex for any exact analysis. The deep intimacy of parts in each tissue corresponds with the union of the whole, with the dominion of common laws, and with that concerted action of all parts, which, in a popular sense, makes up the life of the organic being.

131. It has already been stated, that a knowledge of the minuteness of structure which is supplied by the microscope is practically useless, while the deceptions of that instrument have led to many important errors in physiology and pathology (§ 83). It cannot be depended upon, especially, in exploring soft structures. If it lead to unimportant facts, it is equally liable to betray us into error and fal-

The whole history of that instrument, so far as lacious hypotheses. physiology is concerned, has gone to confirm the foregoing conclusions, which were originally advanced in another work, and has conclusively sustained the opinion of one of the most profound observers

of the present age. Thus:
"Authors," says Bichat, "have been much occupied with the intimate structure of glands. Let us neglect all these idle questions, in which neither inspection nor experiment can guide us. Let us begin the study of anatomy where the organs can be subjected to the senses." "No methodical mind will attend to the minute nature of the muscular fibre, upon which so much has been written. The exact progress of the sciences in this age is not accommodated to those hypotheses, which made general anatomy and physiology a frivolous romance in the last."

Microscopical information, so far as correct, goes to the amount of human knowledge, and to the perfection of science, though it may not contribute to useful ends. But experience shows us that we may not depend, as it respects the microscope, upon the vision of others, especially where a high magnifying power is required. Each must observe for himself; and, as allowed by Ehrenberg, long practice, alone, can assure him of any general accuracy. The laborious student may attend to this accomplishment. But, vita brevis, ars longa; and he will be likely to live the subject of deluded sense rather than of enlightened understanding.

> "Enough is left besides to search and know. Enough is lett besides to search and know.
> But knowledge is as food, and needs no less
> Her temperance over appetite, to know
> In measure what the mind may well contain;
> Oppresses else with surfeit, and soon turns
> Wisdom to folly, as nourishment to wind."—MILTON.

The following is another example in illustration of Milton's principle, and another instance* of the revolutionary spirit of the microscopic observers. I quote from Wagner's "Elements of Physiology

for the Use of Students."

"The study," he says, "of the VARIETIES OF FORM presented by the seminal animalcules ought not to be held as any triffing matter, or as tending to accumulate superfluous details. Most important phys-IOLOGICAL CONCLUSIONS may be BASED on the information thus acquired" (§ 83, b).

It is one of the few correct physiological conclusions to be found

in the writings of Liebig, that

"The most exact anatomical knowledge of the structure of tissues cannot teach us their uses; and from the microscopical examination of the most minute reticulations of the vessels, we can learn no more as to their functions than we have learned concerning vision from counting the surfaces on the eye of a fly."—Liebig's Animal Chemistry.—(§ 83 c, 251, 699 c and d).

When we consider, therefore, the constant deceptions of the microscope, especially in all explorations of soft substances, and the absolute uselessness of any knowledge it may convey as to the recesses of organization, it may be reasonably expected that the time is not

^{*} See article on the Microscope, in Medical and Physiological Commentaries, vol. i., p 699-712; and my Examination of Reviews, p. 6, 89; also, this work, § 515.

distant when all this lumber will be excluded from practical works on physiology, and turned, at least, into a channel by itself.

132. Each simple texture, when united into compound organs, has as much its own specific function as the aggregate compound. It is even more important, in a pathological sense, to regard the individ-

ual textures than the compound organ which they may form.

133, a. A consideration of the tissues in respect to their special character and functions, as well as their obvious anatomical differences, being of the very highest importance to the physiologist and physician, they can be studied advantageously only in these several aspects. Much must, therefore, be now anticipated as to what will be subsequently stated more circumstantially in regard to the properties and functions of life. The student must be prepared with that analysis before he can approach the tissues with any hope of enlightened knowledge. A simple statement of their apparent anatomical characteristics and relations, and of their products, would present a barren field. Nor is it alone their vital attributes which should most engage the attention of the medical philosopher, but he should be equally and simultaneously employed in learning how these conditions are modified in disease. Such, therefore, is my projected plan in relation to the tissues (§ 83, c).

133, b. Every distinct tissue, and often the same tissue as it occurs in different places and connections, and even the different parts of one and the same continuous tissue, possess, respectively, special modifications of the vital properties and functions. Upon these modifications depend the variety of the natural vital phenomena, as, also, very

greatly, those which are morbid.

133, c. But there would be no disease were there not another important condition in the constitution of the vital properties; and this is their mutability. Its final cause is the well-being of organic nature; since, as organization changes in the progress of the plant or of animals to a state of maturity, so must there be an antecedent change in the properties which conduct the development of organs, &c. The same principle is displayed in gestation, lactation, &c. It is this, in connection with the susceptibility of the properties of life to the action of blood and other vital agents, which renders them liable to morbid changes when other causes operate. Such, therefore, is a necessary consequence of the final cause of the adaptation of the properties of life to the influence of salutary agents, and to the varying exigencies of organic nature.

Nor would there be any recovery from disease, but for the same mutability of the organic properties, and their liability to other chan-

ges when yet other causes operate (§ 177, &c., 901).

134. Owing to the peculiarities in the vital constitution of the different tissues, a common disease, as inflammation, is characterized by many peculiarities of symptoms, &c., in the several tissues, respectively. Differences also arise in their constitutional influences, and they may require corresponding variations of treatment (§ 718). This is even true of different parts of a continuous tissue, as the alimentary and pulmonary mucous membrane; where inflammation of this membrane in the nose, larynx, trachea, lungs, fauces, stomach, and intestines, is distinguished by almost as striking peculiarities in the vital signs, and in their constitutional influences, as are the physiological

functions of the different compound organs which it traverses (§ 140

752-754, 780, 783).

135, a. The special modifications of the vital properties in different parts of one and the same continuous tissue is often strikingly denoted by the character of the natural product of the several portions, respectively; as in the tissue last mentioned. Nothing, for example, can be more unique than the gastric juice, a product of all complex animals, while it can be generated by nothing but the mucous tissue of the stomach. Again, in the lungs we meet with this tissue performing the office of excretion; being the only example in which an organ eliminates truly effete matter from venous blood. And here an important analogy occurs to show that the elaboration of carbon is a vital process (§ 316, 419, 827 b). In the uterus the same membrane appears as an organ of excretion in relation to the arteria! blood, but for the uses of the uterus alone; nor is there any thing else in nature that is capable of generating a similar product. But, in all the cases, the analogy which is indicated by the coincidence of anatomical structure is farther confirmed by the universal production of mucus by this remarkable tissue. The anatomical differences are microscopical.

135, b. All the foregoing is delicately exemplified by the great variety of formations which are generated by the granulations that spring from ulcers; since, although in all the cases the granulations appear to be identical in character, we know from their production of parts analogous to such as had been removed by the ulcerative process, that, in every instance, the granulations must have been endowed, respectively, with specific modifications of the organic properties

and shades of difference in organic structure (§ 733 c).

136. In consequence, also, of the foregoing peculiarities of vital constitution, every tissue, and often continuous parts of a tissue (as in the last example), are determined in their results by special vital influences, as well as by any peculiarities of organization. This is denoted by the phenomena where structures are most alike. Owing, also, to the general coincidence in the vital constitution of all parts there are certain general stimuli adapted to the whole, especially the stimulus of heat. The blood has been regarded as a universal stimulus; but, it is only so in relation to the sanguineous system. This fact, it may be now remarked, evinces, what is shown by diseases, a near identity in the vital constitution of all that part of the arterial system which conveys red blood; while, on the other hand, the difference between arterial and venous blood shows a difference in the organic properties of the arterial and venous systems. This has its deep foundation in the whole physiological condition of man and animals, and I may also add, in the whole vegetable tribe (§ 847, c). While every surface has some secreted product adapted to its own special modification of irritability, many of these products may be offensive to other parts. Again, the special irritability of one part may be exactly suited to some product of another part, and this may or may not be a natural vital stimulus, and perfectly inoffensive, to the second part, while it may excoriate all other parts. Bile, for instance, is the natural stimulus of the intestine, but will injure other parts. Venous blood is harmless in the veins, and excites them, more or less, to a contractile action; but is rapidly fatal within the arteries (§ 849). Urine is the natural stimulus of the bladder, but will excoriate most other parts (§ 74, $188\frac{1}{2}$ d, $475\frac{1}{2}$, 500 m, 514 f, $647\frac{1}{2}$, 650, 847 e).

137, a. In this relative sense the animal is filled with poisons; each one of which, however, in its proper place, is not only inoffen-

sive, but indispensable. Here is the principle.

137, b. It is, also, upon the foregoing organic constitution of different parts, and which gives rise to a mutual relation of the different vital agents and products of organs and of the various parts of the organism, that the difference in the effects of remedial as well as morbific agents upon different parts is essentially founded. Wine inflames the mucous tissue of the bladder, &c., but may be good for the stomach. Tobacco smoke is inoffensive when inspired in the ordinary mode; but it is a violent poison when introduced within the alimentary canal. Other agents affect the stomach, or intestines, or liver, or uterus, or bladder, &c., each organ more than the others, and more than other parts (§ 233\frac{3}{4}, 872 c, 838.)

137, c. From not duly regarding these important facts, or from an ignorance, or a disregard of physiology, many agents which have a specific relation to the vital constitution of some tissue in a particular part of the body, as the mucous, for example, are supposed to have the same relation to the tissue in all other parts. Hence the oil of turpentine, copaiva, naphtha, &c., have been abortively or injuriously employed in pulmonary catarrh, phthisis even, diarrhæa, dysentery, &c., mostly for the reason that they exert a specific effect upon the

mucous tissue of the urinary organs.

This great law of adaptation is so universal as to extend throughout the whole domain of medicine, reaching as fully into pathology and therapeutics as it is conspicuous in physiology. If the blood be rendered morbid by morbid states of the solids it never becomes morbific, since there is a progressive adaptation of the vital changes in the solids to such as the solids induce in the blood. And so of various morbid secretions in relation to the parts by which they may be produced. These results, in which the vital properties of the solids are always concerned as the primary cause, are founded in an all-pervading law of the animal economy, and by which, and which alone, nature is enabled to throw off disease (§ 524 d, 944 c, 847 a-h).

137, d. Again, it is one of the most important laws in medicine, that the susceptibility of tissues and organs to the action of remedial agents is more or less affected by disease. Many agents which operate powerfully in certain morbid states, and in certain doses, both locally and sympathetically, may be perfectly inert in the natural states of the same organs. And so of the natural agents of life. The greatness of the effects, also, will depend very much upon the nature and intensity of disease. The same principle applies to the impressions which are made by many remedial agents upon existing states of disease, or upon organs in their state of integrity; by which the diseased or healthy parts are increased in their susceptibility to the subsequent action of the same or other remedies, or to morbific causes (§ 143, e).

137, e. It is, therefore, one harmonious system of laws throughout. Were it, indeed, otherwise, remedial agents could have no existence, and disease, of course, could receive no help from art. These, also, are the beginning of a long series of facts which show us that the effects of all agents, whether morbific or remedial, may be traced to the peculiar impression which they exert upon parts with which they come in contact; and by which, also, we overthrow the whole system

of chemical physiology, the humoral pathology, and the ductrines of

debility, and of cure by the absorption of remedies (§ 847, e).

138. The natural modifications of the vital properties and functions, or the special vital constitution, of any particular tissue, or parts of a continuous tissue, and, therefore, their special modifications in any given disease, conform to the general nature of the complex organ of which the tissue may form a component part.

Certain tissues of a compound organ are far more liable to disease than its other tissues. Thus, the mucous tissue of the stomach is quite liable, the serous rarely, and the muscular more rarely (§ 764, a)

139. Disease of any particular tissue, or parts of a tissue, is apt to be most severe, in its local and general character, according to the importance of the functions of the *compound organ* of which it may form a component part. This, however, is less true of the constitu-

tional influence, than of the local intensity of disease.

140. The sympathetic influences of disease are also greatly determined by the nature of the affection, especially the constitutional effects. Inflammation of the serous, venous, and ligamentous, tissues, disturb the constitution far more than the same degrees of inflammation affecting the mucous, arterial, and muscular, tissues. But much, also, as already said, will depend upon the nature of the compound organ with which the tissue, or part of a continuous tissue, may be associated; though sometimes, where the compound organ is comparatively unimportant, inflammation of one of its tissues may give rise to great constitutional disturbances. Such, for example, is true of some inflammatory affections of the mucous tissue of the throat; and few diseases are more intractable than laryngitis. Much, also, will often depend upon the special modification of disease; as in acute articular rheumatism (§ 525–530).

141, a. Tissues of the same organization are most allied in their vital properties, and hence are most liable to sympathize with each

other in their diseases.

141, b. When a tissue of an organ becomes diseased the properties and functions of the others are more or less disturbed; though the primary disease is not apt to be propagated to them from the tissue first affected. It continues rather in the tissue first invaded. Inflammation, for example, beginning in the mucous tissue of the stomach, will extend along that tissue, so far at least as its connection relates to the stomach, without being often propagated to the other tissues of the compound organ. This principle has a broad foundation, and is owing to the general coincidence in the vital constitution of all parts of the same tissue, and to the differences between the vital states of that and the associated tissues. Exceptions, however, occur more frequently in some parts than in others; as in the lungs, where pleuro-pneumonia is not unfrequent. Nevertheless, in these cases, the simultaneous affection of two distinct tissues of a compound organ may be rather owing to a general predisposition effected by some remote cause than to morbific influences exerted by one tissue upon the other. In other cases, especially of specific inflammation, the disease is propagated directly from one tissue to another, as in scrofula. rheumatism, &c.; but in most other instances by reflex nervous action.

142. For reasons stated in § 133-136, morbific agents may readily excite disease in one part of a continuous tissue when they would have

no effect on another part of it; or may operate more profoundly on one part than on another. And this holds true of the action of remedial agents. The same is also true of the sympathetic influences which may be exerted by disease; and a like principle applies to certain sympathies that fall upon special parts which are immediately continuous with each other, but which are determined, also, by certain special vital relations of the different parts. Thus, the vital relations of the tongue to the alimentary canal being far greater than to the lungs, and as the canal readily sympathizes with other chylopoietic viscera, the tongue is far more sensitive to abdominal than to pulmonary derangements (\S 129 c, i, 689 i, 694 $\frac{3}{4}$).

143, a. Again, there may be varying susceptibilities of the different parts of a continuous tissue (arising from numerous causes not positively morbific), when the same morbific, or remedial, cause will affect one part or the other more in conformity with the acquired susceptibilities, than with the natural modifications, of the vital properties in the several parts, respectively. This is also more applicable to the tissue as it occurs in compound organs not anatomically connected, and to tissues which differ in their organization (§ 783).

143, b. Hence it follows, that, if all the organs be rendered preternaturally susceptible, a general explosion of disease may follow the operation of some cause, which, in sounder health, would be harmless. Under these circumstances, however, disease is most apt to spring up more or less sympathetically, and successively, in one part after another, till all parts may ultimately be brought into some, though variable, forms of disease (§ 514 h, 660, 666, 905). But, in these cases, it generally happens that some of the morbid states abate, or subside, as new ones come forward, the new ones, perhaps, subduing sympathetically the older in the series (§ 804, 905). The system, therefore, is rarely universally invaded by disease, except in idiopathic fever (§ 148, 783). Reflected nervous action applies in all the cases.

Nevertheless, it probably does not often, if ever happen, except in fever, that the primary is the efficient predisposing cause of universal disease, but that disease of one organ proves the predisposing of disease in another; and as one organ after another becomes affected in this manner, they co-operate together in rendering other parts suscep-

tible of disease (§ 644, &c., 715-719).

143, c. In proportion, therefore, as the susceptibility of the system at large is increased by morbid changes, or predisposed by morbific influences, so, in a general sense, will the alterative action of remedial agents be felt in a corresponding manner (§ 137 d, 152 b, 715). By the law of adaptation as set forth in the Medical and Physiological Commentaries (vol. i., p. 649, 653-655, &c.), and in various parts of the present work, the sympathetic influence of any local disease which is felt by distant organs modifies the vital states of those parts in a manner that institutes harmonious relations to the part more profoundly affected; and thus remedial agents will extend their salutary alterative action to such distant parts, and render them the source of salutary effects upon the essential seats of disease (§ 73, 80, 117, 129 i, 133-137, 140, 155, 156, 169 f, 387, 399, 422, 514 h, 524 d, 525, 528, 638, 649 d, 811, 848, 902 f, 905). When the whole system is invaded by disease, as in idiopathic fever, the alterative action of remedies is felt over the universal body (§ 148, 152 b, 222-232, 500,

904 d). It is owing, also, to the same law of adaptation, the same universal, however partial modifications of the vital states which local diseases often induce, that parts remote from the direct seat of disease are protected against all morbific effects from any changes which the blood may undergo as a consequence of morbid action (§ 845, &c.).

Independently, however, of any increased susceptibility of organs, the action of numerous agents upon the stomach may determine influences upon distant parts whose natural state is unimpaired, and these influences may become the source of other impressions upon other parts. Circles of reflex nervous action may be thus engendered universally, by which all parts shall concur in the effects of the gastric irritation which the remedies may institute. In this manner a cathartic or an emetic may bring the whole organism to bear with favorable influences upon some slight inflammation of the throat which had exerted no modifying effects upon other parts (§ 514 h, 692 a, 902 g).

143, d. Again, there are some remedial agents possessing general vital relations to the whole body, especially the several preparations of mercury, and others whose specific relations are more limited, like cantharides, which will affect profoundly the entire organization, or certain individual parts, and alter the condition of their vital states, in the most healthy conditions. These agents, therefore, approach most nearly the truly morbific ones, while they possess the grand characteristic of the Materia Medica of instituting morbid changes which are

of transient existence (§ 1059, 854 d).

144. Many acquired conditions may be transmitted from parents to child, which may thus form a constitutional predisposition to disease; being a permanent and more or less universal modification of the vital properties (though of some parts more than others), which does not properly belong to them; as in scrofula. Here, the absolute remote cause has operated upon the ancestor (§ 75–80, 661).

145. Subjects thus constituted (§ 144) are liable to morbific influences which the more natural do not feel; and such causes as would produce in the natural subject common inflammation of the nose, trachea, &c., will excite scrofulous inflammation in the lungs of the

acquired constitution (§ 650, 659).

146. Hereditary predisposition to disease manifests itself in certain tissues and organs more than in others, according to the nature of the

transmitted constitution (§ 143, a).

147. Sympathetic diseases may spring up in unusual constitutions, when they would not in the more natural. Thus, in certain hereditary conditions indigestion gives rise to scrofulous, rheumatic, and gouty inflammation of parts distant from the chylopoietic viscera. The same principle is also in operation when the vital constitution of parts is modified by habits, climate, age, the development of the generative organs, &c. (§ 542), all depending upon reflex nervous action.

148. Certain causes appear to be capable of affecting, directly and indirectly, all the tissues of the body, as in idiopathic fever; though, in these cases the primary morbific effect is on particular parts, from which it is disseminated by morbific reflex nervous action (§ 649, 665, 666, 760). In these cases, however, it appears not to be a positive state of disease in the part upon which the morbific agents may exert their primary effects, as on the mucous surfaces, which brings the sest of the system into a predisposition to disease; but a predis-

position being established in those primary parts, the impression is of such a nature as to be propagated sympathetically over the universal body; just as when many remedial agents acting upon the mucous surface of the stomach exert powerful influences upon remote organs, but without inducing disease in the gastric mucous membrane. It is, therefore, in idiopathic fever, as well as in numerous local affections, that the parts on which the morbific agents exert their direct effects may not manifest any signs of disease till the explosion of fever takes place; or as when pneumonia, or catarrh, is induced by the action of cold upon the skin; while it often happens that the parts thus originally, but imperceptibly impressed, become sympathetically the seats of absolute disease by the reacting influence of the diseases which had been sympathetically produced through these parts. Very complex circles of reflex nervous action may thus arise. These general affections may be also broken up by the action of a single remedy, as by an emetic, or mercury, &c. (557, 559, 712, 715-719).

149. It is a great and important law, resulting from the physiological considerations now made (§ 133-148), that morbific causes, external or internal, determine disease upon the tissues of one compound organ or another according to the particular virtues of the morbific causes, and in accordance, also, with the natural modifications of the vital properties in every part, and the susceptibilities which they may acquire from other causes (§ 642 b, 722 d, 725, 794, 795, 808). Hence it follows that many of the natural stimuli of

life may become morbific.

150, a. It is a great fundamental law, that a general coincidence exists between the natural susceptibilities of the properties of life to their ordinary stimuli (§ 136), and to those of a morbific, and of a remedial, nature, according to the natural modifications of the vital properties, whether in a general sense (§ 148), or in their relation to particular parts (§ 136); the influences produced conforming, of course, to the natural modifications of the properties of life and the special virtues of the several agents, though modified by the transient or permanent influences which spring from other sources, especially from disease (584, 644–674, 772 c, 826, &c., 847 e, 904).

Such is the inevitable result of the constitution of the properties of life (§ 177). It is, as it were, the great focal point from which all diverges that is embraced in medicine; the bond which unites every

branch of the science.

150, b. All that is here said, and in § 149, is equally applicable to the nervous power, in all its modifications, as an agent in the production and cure of disease, as to agents of a physical nature (§ 222-

 $233\frac{3}{4}$, &c.).

151. It is through the foregoing law (§ 150) that the natural stimuli of life maintain all parts in their precise conditions; through which, also, morbific agents alter those conditions in certain uniform ways, and through which remedial agents establish certain other changes which enable the properties and actions of every part to return spontaneously to their natural states. The law involves an immense range of facts in physiology, pathology, and therapeutics, and groups many other fundamental principles. It should be the point of departure in all our medical researches and reasonings; for it is, as it were, the polar star which will guide us safely upon our difficult and dangerous voyage (§ 794, 795, &c.).

152, a. It follows, therefore, from § 150, 151, that the operation of all things upon the living organism, whether food, heat, cold, blood poisons, the nervous power, or remedies for disease, is upon one common principle, which is relative to the natural constitution of the organic properties. Food stimulates the stomach, and throws a genial sympathetic influence over the whole organism, warming the cold surface as soon as it enters its appropriate receptacle; blood maintains, in the same way, the actions of all parts; poisons and morbific agents, put into the stomach, affect the vital properties of that organ injuriously, when, unlike the case of food, pernicious reflex nervous actions are determined upon other parts, or the same food in excess may do the same. We then introduce into the same organ another class of morbific agents that are less profound in their operation, and which prove remedial in certain doses, and therefore establish, through the same principle, a salutary change in the same properties which other poisons had affected injuriously (§ 638, 642 b, 854).

152, b. It is also worthy of repetition, that such is the analogy between morbific and remedial impressions, that the organs which sustain the former are thus rendered susceptible of the latter, when they might be otherwise insensible to the same remedial agents, in their appropriate remedial doses. Such is the harmony of the laws of nature; such their great final causes (§ 524, no. 3, d). For the same reason, also, many of the natural agents of life, such as the ordinary kinds of food, may be intensely morbific in most of the diseases of man (§ 849). Or, again, the agents which heal in their remedial doses may establish severe forms of disease when administered in health.

153. Through the law of development, the tissues undergo natural modifications in their structure and vital endowments at many periods of life. In infancy, the organs are imperfectly developed, though the properties and functions of organic life, unlike those of animal life, are strongly pronounced in many of the viscera. A relation obtains, however, in organic life, between the properties and functions and the relative size of organs (§ 159).

In childhood, there is another well-marked change. In adolescence, another; when the organs become mature. In old age, another; when life is naturally on the decline.

154. The foregoing stages of development (§ 153) are not sudden,

but gradually progressive.

155. The changes of organization (§ 153, 154) are preceded by corresponding changes in the vital properties, upon which the former depend (§ 445, f). This principle, too, like all others which relate to organic life, whether in health or disease, is universally true under any given combination of circumstances. It is true of the development of all tissues and all organs, and all other products, from the beginning of conception to the end of life. Hence, also, the variety in the remedial or morbific virtues of many plants, at different stages of their growth. As structure varies, the vital properties have undergone modifications, in conformity with that order of Design which was instituted, that where one specific end is accomplished, and others are to be fulfilled, the powers by which these final causes are to be accomplished shall have their necessary adaptations. And while, also, the vital properties, under all their natural modifications, are so constituted as to receive certain exact impressions from the natural stim-

uli of life, that vital actions may be determined according to the purposes ordained, so also will morbific and remedial agents be varied in

their influences (§ 129 i, 387, 980).

156, a. The foregoing variations (§ 153-155), therefore, give rise to new dispositions to disease in many parts, and are productive of modifications of former diseases, or the latter disappear. This, as we have seen, is a necessary consequence of the physiological changes, since the same properties which carry on nutrition and growth carry on all diseases. The relations of vital and morbific agents move on, pari passu, with the natural changes in the properties of life; and remedial agents undergo corresponding modifications of action.

156, b. The great law of adaptation is forever present to the eye of the naturalist; and when the same subjects are contemplated in a moral sense, the same evidences of Design meet him at every glance of the mind. Take an example of a compound nature, a universal physiologico-moral phenomenon in which our present topic is involved. Thus, no sooner was man created than he was doomed to obtain his subsistence by the sweat of his brow. Roots, grains, fruits, &c., were, therefore, as far as the wants of animals would allow, created mostly in an unedible condition, but rendered susceptible of the requisite improvement by cultivation; and to carry out the great purpose, the nature of soils, air, water, &c., were made subservient (§ 74, 80, 117, 137, 143, 155, 169 f, 266, 384, 385, 387, 399, 409 f, 422 514 h, 524 d, 525, 526 d, 528, 638, 733 b, 847 g).

157. Organs are softest and most fluid at the beginning of their development, and increase, progressively, in density through life. The

animal ovum is scarcely more than an organic fluid (§ 67).

158. Vascular action is promoted by the greater fluidity of organs, and vice versa (§ 142). Inflammation is in part, therefore, more intense and rapid in infancy and childhood than at later periods, which, with other causes, gives rise to the necessity of great promptitude of remedies. Other causes attending the vital conditions of old age render equally important a decisive treatment of the severe diseases that may befall that age (§ 574, &c., 1009, &c.).

159. The proportional size of organs varies at different stages of life. The cerebro-spinal system, for example, is largest in childnood. Hence a greater development of the organic properties in those parts, and a greater consequent liability of the brain to inflammatory and congestive affections, and to hydrocephalus. The large proportional size of the nervous and arterial systems affects the physiological and pathological condition of all other parts; giving activity to nutrition, and susceptibility and intensity to disease.

The glandular tissue of the liver has the largest proportional size in infancy; but not so the venous system of the liver. Hence, again, the glandular function of that organ is especially liable to derangement in infancy, and its venous tissue to congestion at more advanced

ages.

It is also important to understand, that the veins, in a general sense, "have a real inferiority as it respects the arteries, during the first periods of life."—BICHAT. There are some exceptions, especially in the brain.

160. What has now been said of the modifications of the vital constitution of different tissues and organs may be illustrated by the rel

ative liability of different tissues, and parts of common tissues, to some given disease, by the relative danger of that disease as it may affect the different parts, and by the effects of some remedial agent upon the various parts, respectively. The remedy may be loss of blood, and the supposed disease inflammation. The statement may be conveniently made in a tabular form, while, also, it may be converted to practical uses (§ 711).

161. The tables are intended in a general sense, and suppose the constitution to be naturally sound. If hereditary predispositions to disease exist, as in scrofula, or if the constitution be affected by intemperance, or by previous diseases, &c., the order of liabilities to inflammation, &c., as marked in the first table, will be more or less affected. In the scrofulous constitution, for example, instead of the

mucous, the lymphatic tissue may be most liable.

162. The tables will be more or less modified by age. Thus, the veins of the pia mater are more liable to congestion in infancy and childhood than any other part of the venous texture. This liability afterward decreases, and returns at the age of fifty and upward, resulting in cerebral hemorrhage (§ 805).

PHYSIOLOGICAL AND PRACTICAL SUGGESTIONS.

Tissues most liable to disease, especially to inflammation, in the order of arrangement:

- 19. Bladder.
- 20. Mucous texture of bronchiæ.
- 21. Mamma, testis, parotid gland.
- 22. Absorbents of extremities.

163. In the treatment of disease, therefore, we should consider the precise pathology of each affected tissue, the natural vital peculiarities of the affected tissue in the compound organ, its general character as well as that of the compound organ in the animal economy, the influences which its morbid state exerts upon the other tissues in a compound organ, its own morbific influences and the combined influences of the compound organ upon other parts, and how the remote sympathizing parts may react, or shed an influence on yet other parts. And then follows not only the general plan of treatment, but all that nice discrimination of cathartics, emetics, alteratives, and other groups of agents possessing, in their individualities, respectively, analogous virtues, their combinations, alternations, precise dose, frequency of repetition, &c. (§ 675, 685, 686). The same variety of considerations are to be made when the condition of diseased parts may undergo changes, favorable or unfavorable, from the operation of remedial agents.

We are mostly assisted in the foregoing inquiries by comparisons of the morbid with the natural vital phenomena and physical products of each part, and the whole collectively. We also acquire much of our knowledge of the natural constitution of individual parts by observing the deviation of their phenomena when acted upon by morbific or remedial agents. The phenomena are then more strongly pronounced than in health, or new ones are developed. Indeed, it is sometimes through morbid conditions only that we acquire a knowledge of some of the important physiological conditions; as, for example, the existence of common sensibility in all parts. Hence a corollary, that none but an observer of disease can expound the natural conditions and laws of life (§ 685, 686, 848).

THIRD DIVISION OF PHYSIOLOGY.

PROPERTIES OR POWERS OF LIFE.

164. A VITAL, or peculiar governing principle or power, in organic beings, has been recognized by all the most distinguished medical philosophers at all ages of the science. It is the fundamental cause of growth, nutrition, and of all other phenomena of organic beings. It is, in all but the vulgar acceptation, synonymous with the term life; and life, therefore, is a cause, and not an effect, as has been assumed by many distinguished physiologists, and as taught by chemistry.

165, a. "Until it is proved," says Andral (the restorer of the humoral pathology), "that the forces which, in a living body, interrupt the play of the natural chemical affinities, maintain a proper temperature, and preside over the various actions of organic and animal life, are analogous to those admitted by natural philosophy, we shall act consistently with the principles of that science, by giving distinct names to those two kinds of forces, and employing ourselves in calculating the different laws they obey."—Andreal's Pathological Anatomy.

And, to the same effect, the distinguished organic chemist, Liebig,

the chief of the school of pure chemistry ($\S 4\frac{1}{2}$):

"There is nothing to prevent us from considering the vital force as a peculiar property, which is possessed by certain material bodies, and becomes sensible when their elementary particles are combined in a certain arrangement or form. This supposition takes from the vital phenomena nothing of their wonderful peculiarity. It may, therefore, be considered as a resting point from which an investigation into these phenomena, and the laws which regulate them, may be commenced; exactly as we consider the properties and laws of light to be dependent on a certain luminiferous matter or ether, which has no farther connection with the laws ascertained by investigation."—Liebig's Animal Chemistry.

So, also, Carpenter, Roget, and other eminent chiefs of the physical

school (§ 64).

And thus, the eminent Müller, who leads in the school of chemico-

vital physiology:

"The only character that can be possibly compared in organic and inorganic bodies, is the mode in which symmetry is realized in each." "Whether the vital principle is to be regarded as imponderable matter, or as a force or energy, is just as uncertain as the same question in reference to several phenomena in physics. Physiology, in this case, is not behind the other natural sciences; for the properties of this principle in the functions of the nerves are nearly as well known as those of light, caloric, and electricity, in physics."—MÜLLER'S Physiology.

Finally, we have the pure vitalist, teaching the same doctrine;

though, with greater consistency. Thus:

"Physiology," says Bichat, "would have made much greater progress, if all those who studied it had set aside the notions which are porrowed from the accessory sciences, as they are termed. But, these sciences are not accessory; they are wholly strangers to physiology, and should be banished from it wholly." "To say that physiology is made up of the physics of animals, is to give a very absurd idea of it. As well might we say that astronomy is the physiology of the stars."—Bichat's General Anatomy, &c.

Tiedemann, too, was right in saying that,

"All the qualities of organic bodies should be looked upon as the effects of the vital powers. Even those phenomena seen in them, which they exhibit in common with inorganic bodies, undergo modifications of their specific action, and should be considered subordinate to the vital powers."—Tiedemann's Physiology, &c.

There is not, indeed, in the whole range of medical literature, one author, however devoted to the physical and chemical views of life, who does not evince the necessity of admitting a governing vital prin-

ciple as a distinct entity, distinct from all other things in nature. I say, there cannot be produced one author of any consideration, who does not summon to the aid of his discussion a vital principle whenever he touches upon the abstract phenomena of life. And this I have abundantly shown by an extensive range of quotations in my various pub-

lications (Except § 1034).

165, b. We are constantly asked, how we know the existence of the vital properties or powers? Again, I say, precisely by the same means as the advocates of the chemical and physical philosophy of life defend their knowledge of the forces which govern the inorganic world. The question is important, as implying that physiologists either do not arrive at their knowledge of causes through their effects, or, that there is nothing different in the phenomena of organic and inorganic beings. What would the metaphysician say, were we to ask him for any other demonstration of mind than its manifestations; or the mechanical or chemical philosopher, should we demand any other evidence of gravitation, magnetism, chemical affinity, &c., than the effects which they supply? And do we not distinguish one from the other, and regard them as wholly distinct forces, by the difference in their effects? The proof is clear and tangible, in all the cases. Where the results of power differ so materially from each other, it is as good a ground of argument, that the phenomena depend upon specific powers in one case as in the other; and, if it be "a cloak of ignorance" in either case to assume the existence of powers, it must surely appertain to him who attempts an explanation of the phenomena by assuming forces with which such phenomena have no known connection (§ 175, bb, 1085).

166. Many of the eminent ancient physicians considered the vital principle an intelligent agent; and even Hunter has been supposed, though erroneously, to have been of that opinion. Some distinguished physiologists, of the present day, are inclined to regard the soul as that agent. Others confound it with the Deity;* while yet others, confounding the Deity with Nature, fall into a labyrinth of absurdities.† Others suppose the vital functions alone to constitute life.‡ The ancient physicians generally distinguished the vital principle from

the soul, and regarded both as immaterial (§ 175 d, $350\frac{3}{4}$ k).

167, a. The vital principle was early known under the names of Anima and Calidum Innatum. It was greatly lost sight of in the "dark ages," but reappeared among the earliest restorers of learning, when it took the name of Anima Vegetans, as significant of its organizing power in plants and animals. The eccentric philosopher, Paracelsus, substituted the name of Sidereal Spirit, to suit his dogmas of planetary and demoniac influence. Then came Van Helmont with his innovation of a Spiritus Archaus, an immaterial principle, which he located in the upper orifice of the stomach. It presided over the body in a general sense, and had under its command several subordinate spirits (one for each organ), to execute the orders of the great spirit. But, like Paracelsus, he expounded much of his physiological results upon chemical principles, and had no definite conceptions of the office of his Archæus. Stahl followed Van Helmont with his Rational Soul,

^{*} See my article on the "Vital Powers," in Medical and Physiological Commentaries vol. i.; and my "Essays on the Philosophy of Vitality."

† See my "Examination of Reviews," p. 43.

‡ Comm., ut supra

and Lord Bacon had entered the field in defense of a vital principle. Then came Haller, with his great philosophical and practical distinction of the Vis Insita and Vis Nervea. Here we enter into the midst of the profound theories of irritability and sensibility, which had been suggested by Galen (§ 476, b). Glisson, too, had forced his way into the laws of irritability; and Baglivi had already dealt his fatal blows upon the humoral pathology. We may, therefore, date the progressive and substantial foundation of vitalism and solidism from Baglivi

to Haller; a period of about one hundred years.

Des Cartes led the way in rejecting altogether, for awhile, the vital powers, in which he was aided by the hypothesis of a nervous fluid, which appeared about his time. The doctrine then followed, as a consequence, that matter acquires vitality in virtue of a peculiar organization, and this became an easy step to the atheistical doctrine of spontaneous generation. Then came up the view as set forth by Monro, Sir Humphrey Davy, and others, analogous to the Cartesian, that a living principle pervades the universe, and governs all things. Some of this school suppose the universal principle to be subordinate to the Deity; but a greater number, like Carpenter, Prichard, and especially many of our present geologists, as Lyell, &c., regard it as the Deity Himself, whereby the latter, either directly or by implication, confound nature with God. The doctrine becomes, here, either atheistical or of a direct atheistical tendency; and we have, as a renewed consequence, the assumption of spontaneous generation.*

167, c. Those great luminaries, Hunter and Bichat, came forward in good time to rescue the philosophy of medicine from the degradation with which it was threatened by chemistry and physics, and have

left an impregnable shield to all future ages.

167, d. Tiedemann, too, soon after appeared with his "Physiology of Man," in which the doctrines of life are ably expounded, and which must be ranked as one of the productions of an original mind. Tiedemann could not believe that there was any sincerity in the absolute rejection of a peculiar governing principle of living beings. "However different," he says, "may be the names chosen by physiologists and physicians to designate this power, however various the ideas they attach to it, yet all must agree on the essential point, that of regarding it as intended to maintain living bodies, vegetable and animal, and all their parts, during a certain space of time, in a state of integrity, in the composition, organization, and vital properties that are peculiar to them, and to render those bodies capable, at a certain period of their existence, of producing beings of the same species as themselves, which beings are confined to the same determinate mode of formation and development, and exhibit similar phenomena." "We are bound, therefore, to consider the principle which presides over those different acts, as a power inherent in all parts of living beings, and we cannot assume that, either in vegetables or animals, it is limited to any one part or parts. All the parts of a plant, the roots, stem, branches, leaves, flowers, wood, and bark, are nourished. Nutrition takes place in all the tissues and organs of animals. The con-

^{*} See Medical and Physiological Commentaries, vol. i., p. 25, and vol. ii., p. 124-140. Also, "Examination of Reviews," p. 43; "Notice of Reviews," p. 4; "Essays on Vital ity," &c., p. 17.

tinual tendency of this power to preserve the individual and all its parts, forms the prominent character of individual life, and is presented to us as the most important internal condition of life. This power not only converts the alimentary matters, drawn from without, into nutritive fluids, endowed with special properties and assimilated by it, but it also introduces them into the solid organic form, determines and regulates the composition, the organization, and the vitality of parts. Every living body is exposed to external influences, which urge it to manifestations of activity. Every one, however, under certain external circumstances, retains its form, its composition, and activity. Certain external impressions, however, of a mechanical or chemical nature, and divers organic matters, vegetable and animal poisons, are able to annihilate this power,* and thus to cause the death of the living bodies on which they operate.'

167, c. Next came the illustrious Müller to aid in arresting the almost universal onslaugh, in Europe, that seemed to threaten the extinction of every sage in medicine from Hippocrates to the exit of Bichat. Under the magic wand of Andral the venerable doctrine of humoralism reared its portentous form; while Louis substituted morbid anatomy for the science of pathology, and Liebig, and his school

with fire and acids, overrun the whole domain of medicine.

Although Müller employs the language of Stahl, in relation to a vital principle, I think it rather designed as a forcible mode of expression, than as imputative of intelligence. Thus, "this rational creative force," he says, "is exerted in every animal strictly in accordance with what the nature of each part requires." The fact is truly stated; but it reposes on great laws of organization, not upon intelligence. That such is Müller's view appears from another expression, that, "the formative or organizing principle is a creative power, modifying matter blindly and unconsciously." The radical fault of this philosopher consists, like that of Van Helmont, Stahl, Hoffmann, and Paracelsus, in referring many vital results of organic beings equally to a "vital creative principle" and to chemical forces.—See Muller's Physiology.

167, f. So remarkably different, however, are all the results of life from those of dead matter, that some of the shrewdest physiologists, of our own day, can scarcely avoid the chimerical theory of Van Hel-

mont. Thus, even Marshall Hall:

"The principle of action in the cerebral system," he says, "is the $\psi v \chi \eta$, or the immortal soul. Upon the cerebrum the soul sits enthroned, receiving the embassadors, as it were, from without, along the sentient nerves; deliberating and willing, and sending forth its emissaries and plenipotentiaries, which convey its sovereign mandates, along the voluntary nerves, to muscles subdued to volition."†—(Hall

* See "Examination of Reviews," p. 26-28; also, this work, § 189 b, 350\frac{3}{2}b.
† I have somewhere seen it suggested that the doctrines of vitalism may be applied in support of animal magnetism. But, while vitalism is fundamentally opposed, even to speculative theory, and rests alone on the absolute phenomena of organic beings, it is not less true that, with rare exceptions, the medical advocates of animal magnetism are, as in ancient times, among the physical theorists of life (§ 844). Dr. Elliotson is of that denomination. (See Med. and Phys. Comm., vol. ii., p. 137, 138.) And, although I have, in the foregoing work (vol. i., p. 632), expressed my opinion of the countenance which has been given to this imposture by distinguished members of the medical profession, I will add my entire concurrence in the following sentiments by Hannah More. In a letter to Horace Walpole, dated 1788, she remarks, "I give you leave to be as severe as you please on the demoniacal mummery which has been acting in this country; it was, as usual with

on the Nervous System.) Here I suppose the "emissaries and plenipotentiaries" to be nothing more than the nervous power, a property

prodigies, the operation of fraud upon folly. In vain do we boast of the enlightened eighteenth century, and conceitedly talk as if human reason had not a manacle left about her, but that philosophy had broken down all the strong-holds of prejudice, ignorance, and supersition; and yet, at this very time, Mesmer has got a hundred thousand pounds by animal magnetism in Paris. Mamadue is getting as much in London. There is a fortune teller in Westminster who is making little less. The divining rod is still considered as oracular in many places. Devils are cast out by seven ministers. Poor human reason, when wilt thou come to years of discretion!" (§ 844.)

I may also add the following extract from the New York Journal of Medicine for March,

" New York, Feb. 14, 1845.

" MR. EDITOR,

"Dear Sir—In a letter of the 11th inst., addressed to myself, you desire me to state what I witnessed of the firmness of a young gentleman, upon whom the operation of exsection of the inferior maxillary bone was performed by Prof. Mott, 'and the reflections to which it gave rise, as bearing on the subject of alleged surgical operations without

pain in the mesmeric state.'

"The case to which you refer is briefly reported in the January number of the New York Journal of Medicine, by some person, who, like myself, was present at the operation. The subject is there stated to have been a fine intelligent young man, whose he-

roic deportment greatly facilitated the operation.'
"Perhaps it is enough that I should have quoted the expressive language of one, who appears to have looked on with the same admiration as myself; though these examples of heroic deportment are common enough in the walks of surgery, especially among females; and that, too, without mesmeric imposture. The same eminent surgeon, who operated in the case which is the subject of these remarks, will tell you that he has extirpated many breasts, rendered highly sensitive by carcinomatous disease, without observing any evidence of pain. But there was something in the case of Mr. Baker, which certainly better deserved the encomium of 'heroic,' than any thing I had ever before seen, or heard of, or even imagined as within the compass of human fortitude.

"This case, therefore, is interesting at this moment, as evincing a perfect capability of enduring the most intense, and sudden, and prolonged pain, without emotion, and as forming a test by which the subject of alleged surgical operations without pain in the mesmeric state, will receive the explanation which you seek.

"The case is also physiologically interesting, and interprets the composure of those or.

ganic movements, under similar conditions, which has been set forth in behalf of animal

"To appreciate properly the 'heroic deportment' of young Baker, you must imagine yourself to have been a spectator; follow the able surgeon in all the capital steps, and in all the minor details of the operation, and watch attentively the 'deportment' of the subject. He was laid at a convenient elevation upon a table, his feet crossed upon each other, and his hands lapped. I mention this position, because he did not move his feet, nor displace his hands during the operation.

"Now observe the operator; first, making a long and deep incision among the muscles of the neck, and then tearing his way down to the carotid artery, and throwing and tying the ligature. It was, in itself, one of the most capital operations in surgery; but, owing to the dexterity with which it was performed, and with an operation still before us far more difficult, and tedious, and dangerous, this grand step toward the exsection of the jaw lost much of its usual interest to the spectator. But it was not the less painful to the

lost much of its usual interest to the spectator. But it was not the less painful to the sufferer; who, however, sustained it without betraying the slightest evidence of pain. "Next came the circular incision, reaching all the way from the joint of the maxillary bone, down along its lower edge, up to the middle of the chin. This was done by one rapid, immense sweep of the knife; but there remained the same imperturbable composure of the patient. Not a sigh, not a groan escaped, no muscle moved—the very eye did not wink. And then followed, as you may well suppose, a prolonged, tedious, painful dis-section, in which it became necessary to exasperate the suffering by securing many bleeding vessels; till, finally, the operator was ready for his saw. But nothing had yet hap-pened to elicit a single manifestation that the patient was not in a profound slumber, excepting that his eyes were open, and that he occasionally swallowed.

But, before sawing the bone at the middle of the chin, it was necessary to remove one of the incisor teeth, and this was so firmly rooted that a straight forceps slipped in the hand of a capable assistant. Another pull, however, brought with it the tooth; but in neither attempt was there any more indication of suffering than in drawing a nail from a

"Then came the process of sawing, and this was calculated to greatly annoy the patient from a slight accident which happened to the saw, and which prolonged this part of the operation. Still, however, the same 'heroic deportment' distinguished the patient forbearance of the sufferer, the same unexampled complacency continued to mark every lineament of his face, his very eye displaying nothing but gentleness, softness, and calm resignation.

of the vital principle of animals, and whose modus operandi in developing voluntary motion I have endeavored to expound in sections 233.

245, 500, d, and references there.

167, g. For the proof of the existence of a vital principle, and of the government of organic beings by laws peculiar to themselves, as derived exclusively by myself from their composition, see that division of this work, and my Essays on the Philosophy of Vitality; and for the proof which I have offered as founded on the phenomena of life, see Essay on the Vital Powers, in Medical and Physiological Commentaries, vol. i., p. 1-119.—Also, Rights of Authors, p. 912.

168. It is practically useless to investigate the nature of the vital That nature, however, may be as well inferred through the medium of its phenomena, as the nature of the most tangible objects. The opinion of Müller commends itself to every right-thinking

"Whether the vital principle," he says, "is to be regarded as imponderable matter, or as a force or energy, is just as uncertain as the same question is in reference to several important phenomena in physics. Physiology, in this case, is not behind the other natural sciences; for the properties of the vital principle are as well known in the functions of the nerves, as those of light, caloric, and electricity in physics." "But, without, in the remotest degree, wishing to compare the vital and mental principles with the imponderable agents, we must express our conviction that there is nothing in the facts of natural science which argues against the possibility of the existence of an immaterial principle independent of matter, though its powers be manifested in organic bodies—in matter."—Müller's Physiology.

"The bone being separated at the chin, the dissection was resumed among the important parts, and though conducted with all possible skill and rapidity, it was necessarily tedious, as well as hopelessly painful, and, therefore, still calculated to try the firmness of the stoutest heart. A great extent of all kinds of tissues was divided, and, of course, no small proportion of nerves. Bleeding vessels continued to be secured, the difficult division of the articulating ligaments performed with as much facility as its difficulties would admit; and after the removal of the jaw, remaining portions of diseased muscle, &c., were cut away, and which tended not a little to embarrass that 'heroic deportment' which had marked every stage of this great and triumphant operation. From its beginning to its ending, which occupied one hour and a half after the first incision till the final extirpation of ell the diseased mass, the sufferer did not manifest the slightest evidence of pain, or of impatience, or of fatigue, either by language, gesture, expression of countenance, winking, groaning, sighing, or any other imaginable method by which the mesmerite might be disposed to evade the overwhelming rebuke which the recital of this case cannot fail to inflict on his love of the marvelous, or his love of mischief, or his yet more culpable designs on human credulity.

"I have said that there was something physiologically interesting in the foregoing case beyond its simple merit of an 'heroic deportment,' and that it goes to the very depths of

mesmeric assurance and duplicity. It was this:

"On feeling the pulse of the patient twice during the operation (the last time after the lapse of an hour), I found it calm, undisturbed, and with about the same frequency it had before the operation was begun. This proves to us what I have before expressed, that it is not pain, but the consequent mental emotions which affect the organs of circulation, whether the heart or blood-vessels.

"Thus ended an operation, unequaled in the annals of surgery; alike triumphant to the surgeon, to American Genius, to the admirable subject, to the cause of truth, of moral-

the sargeon, to American Consider, and the sargeon of sound religion.

"If you desire it, you may publish the foregoing statement, to which I should add some "If you desire it, you may publish the foregoing statement, to which I should add some pression of one of the greatest nuisances that has yet infected the moral and reflecting pression of one of the greatest nuisances that has yet infected the moral and reflecting the same property. Thave, however, some developments in reserve, which will problem. part of the community. I have, however, some developments in reserve, which will probably see the light when the parties interested may be beyond the reach of greater reproof or mortification.

"I remain, very truly, your friend and obedient servant,
"MARTYN PAINE."

In the language of Liebig, "In regard to the nature and essence of the vital force, we can hardly deceive ourselves, when we reflect, that it behaves, in all its manifestations, EXACTLY like other natural forces; that it is devoid of consciousness, or of volition, and is subject to the ac-

tion of a blister" (§ 165, a).

169, a. We know, however, but little of the nature of the principle of life, and as little of the most obvious material substances; but, while this proposition is sufficiently plain, it is extensively argued that the vital principle, or organic force, has no existence, because it is not obvious to the senses. Thus neglecting its infinite phenomena (our only knowledge of the most sensible existences), the age has run into a materialism that takes in its way the soul itself.

Our great interest lies in the phenomena of nature. Through these phenomena their causes may be sought; their nature but very imperfectly. We can only describe matter by its manifestations; and so of the soul, and the principle of life. Of the nature of the soul, however, we have, as it respects its spirituality and some other

important attributes, a special Revelation.

169, b. If organized beings possessed a principle of life that could, like light, be seen, they would then be allowed to be governed by this agent, and we should be relieved of the encumbrance of the physical and chemical hypotheses. But, though no such principle address itself to the sight like electricity or light, its existence is far more variously attested by other phenomena, and more so than all the other powers of nature; and these phonomena being wholly different from such as appear in the inorganic world, it is prima facie evident that powers or properties which are predicated of them carry on the processes of health and disease; while the scrutiny of ages has never produced a fact in opposition.

169, c. Indeed, with so much light upon our subject, so much of fact to substantiate our conclusions, it would seem highly probable that all the facts which may be raised in opposition have no relative bearing, and that they are brought forward in the spirit of hypoth-

esis.

169, d. The more comprehensive a law may be, the more readily is it known and determined, and the less likely is it that apparently conflicting facts will arise. Whenever such are produced, it is owing to a proper want of investigation. The facts are examined superficially; and the speculative or the credulous mind seizes upon some prominent characteristic, and pushes its opposition to nature under the spur of novelty, or the delight of discovery, or the goad of

ambition. (See Correlation of Forces, p. 921, § 1085.)

Since, also, we seek, alone, for the existence and the nature of causes by means of their phenomena, he is no philosopher who refuses an inquiry into causes from want of other means of information. The objection has never been raised in any science excepting medicine; but here we are told by many that we have no means of reaching even the existence of the properties of life as contradistinguished from those of inorganic matter. It is this blindness, in part, which refuses to apply to the science of life the universal fact, that the phenomena are the only index to the forces which govern the inorganic world, that has embarrassed the progress of medicine, and encumbered it with a spurious philosophy.

which true philosophy will recognize as her own, I shall go on with an investigation of the properties of life, as the source of all vital phenomena, of all morbid conditions, and which constitute life itself, and lie at the foundation of medicine. I shall enter far more exten sively into an analysis of those properties than any other writer, shall set forth original views as to the character and office of the nervous power, and as to the mode in which this power participates in the operation of remedial and morbific agents, and endeavor to show, also, that, in proportion as philosophy may depart from the deductions which are founded on the phenomena of living beings, so must all such philosophy be fundamentally false, and become the unavoidable cause of practical errors of the highest moment (Rights &c., p. 912).

169, f. Nor is it a small part of the proof that vitalism is founded in nature, that it is consistent throughout; seeking no multiplication of causes, but serving as an impregnable and universal foundation for every fact and every rational principle in physiology, pathology, and therapeutics; and, therefore, uniting all the principles relative to life, health, disease, and the art of medicine, into one consentane ous, harmonious whole. What a contrast with the mechanical and chemical speculations, or those commingled with vitalism! What a boundless source of stupendous philosophy for the votaries of one; what unmitigated confusion, and corruption of knowledge, and misapplication of mind, for the disciples of the other! How truly, and with what sublimity on the one hand, and imbecility on the other, is here exemplified the great distinction between man and his Creator, that the former devises in parts that may have no congruity, while the latter perfects the whole and all together (§ 63, &c., 74, 80, 117, 137, 143, 155, 156, 266, 323-326, 387, 399, 514 h, 524 d, 526 d, 638)!

170, a. The vital principle is a whole, in respect to its substantial nature, and is common to vegetables and animals. Organic matter, or an organized substratum, is necessary to its existence; and, since the perpetuity of organic matter depends upon the vital principle, it is manifest that both were brought into being without the agency of each other. The vital properties cannot be generated by matter, since upon them the existence of organization depends, nor is there a single phenomenon that indicates their presence in inorganic substances; nor can they be produced by the forces of physics, since they are perfectly incapable of restoring the structure, or even its elementary composition, after the organized matter is decomposed, or, of reanimating the machine before decomposition has begun; while, on the other hand, these are the forces which lay waste the structure, and only so, after the signs of the vital properties shall have totally disappeared (§ 1079 b, 1085).—Notes Pp p. 1142, Qq p. 1145.

This unavoidable deduction goes far in confirming the Mosaic account of the different steps observed by the Almighty in the creation of living beings; that the sensible structure was first produced, and the spiritual and vital existences superadded.* The rudiments of that organization have been perpetuated in connection with the properties of life since they came from the hands of the Creator, and are the present source of all animated beings. Any doctrine adverse to

 $^{^{\}bullet}$ See Medical and Physiological Commentaries, vol. i., p. 86–92. F

this is not only atheistical, but is opposed to all the suggestions of reason* (\S 74, $350\frac{3}{4}$ k). Nor is this all. The varieties in the different tissues of each animal, and of every plant, all the modifications of the vital properties in each species of animals and plants, in each tissue, and in every part, as already set forth (\S 133, &c.), and to be yet expounded, all the various functions that correspond to the modified structure and vital properties, all the secretions, even to the odor of flowers, &c., are exactly the same now as at the day they were called into being. This shows us that the properties and laws by which organic beings are governed, though infinitely varied, are as precise as the principle and laws of gravitation, as the conditions of the solar beam and the laws which they obey.—Note Pp p. 1142.

170, b. Again, the moment inorganic matter is brought into a state to receive the vital principle, however low in degree or energy, it must be exalted to an organic condition. If chyle, blood, semen, the gastric juice, &c., possess life, so, also, must they possess an organic state. This, indeed, is obvious from what we have seen of the

manner in which their elements are united.

170, c. The living principle appears, therefore, to be neither the result of organic compounds, as supposed by Hunter and others, nor, as stated by Prout, Millengen, and others, the primary cause of organic conditions. Both have coexisted since they were the product of Creative Power, both are necessary to the vivification of dead matter, and the co-operation of both to the farther development of each.

171. The vital principle appears entire in parts when separated from their connections, if such parts be constituted with the requisite structure for independent nutrition (§ 304). Hence the development of the egg, the germination of seeds and flower-buds, the growth of shoots, and the multiplication of polypi from portions of the animal.

Müller, and others, suppose the vital principle to be divisible in such cases; but this construction regards the principle too much in the light of ordinary matter, and too little in that of a specific substance endowed with a variety of properties. These properties, so far as necessary to organic life, are implanted in every part, and each part may be regarded as a whole as it respects its own organic condition. In simple beings, therefore, where no great complexity of organs is necessary to the great final cause, nutrition, many parts of such beings may be capable of carrying on the process independently of the rest (§ 299, 302, 304, 322). It is probable, therefore, that the vital principle, in the foregoing cases, is no more "divided" than the soul or instinct as implanted in the ovum.—Medical and Physiological Commentaries, vol. i., p. 85, 87.

172. The principle of life, or life itself, may be summarily defined as a cause, consisting of certain specific properties, appertaining to organic matter, capable of being acted upon by external and internal physical agents, by the nervous power, and bymental causes, and of thus being brought into a state of action itself, and in no other way. Its action is exerted upon the organism, and upon certain external substances, as upon food. In the former case its action gives rise to motion, upon which all the functions depend; in the latter its operation

^{*} See Med. and Physio. Comm., vol. ii., p. 123-140. Also, "Examination of Reviews" p. 43; and "Notice of Reviews," p. 2, &c., in "Med. and Physiolog. Comm.," vol. iii. -Also, § 1079 b, 1085.

is through the medium of the gastric juice in animals, but is more obscure in vegetables. The principle is creative so far as it combines the elements of matter in peculiar modes, and arranges the compound molecules into tissues and organs, and in modes identical with those which came originally from the Creative Energy of God, Who thus far imparted to the principle of life a formative endowment. principle is capable of protecting the matter which it endows against the decomposing influences of all the physical agents by which it is naturally surrounded, while the extinction of the principle exposes the organic substance to an intestine chemical dissolution, and to the decomposing action of surrounding agents, which proceeds with a rapidity without parallel in the natural state of the inorganic world. principle is also susceptible of certain limited changes from the influence of causes, mental and physical, which constitute the essence of disease; while other causes are capable of modifying the morbid changes in such wise that the principle of life takes on a restorative energy, through which it recovers its normal condition. The properties of the vital principle are variously and naturally modified in different parts, and undergo natural modifications at certain stages of life, giving rise to changes of organization, &c. (§ 62, 64, 133, &c.). These natural modifications will be farther explained in all the detail which is demanded by one of the most important topics in physiology; and I now proceed to the various specifications relative to the principle of life.

173. It is the special province of the vital principle in plants to combine the elements of matter into organic compounds; while in animals it can only appropriate compounds of an organic nature. This is a fundamental distinction between the two departments of the organic kingdom; from which it appears that plants are indispensable

to the existence of animals (§ 1052).

174. The vital principle is subject to extinction, and this constitutes death. When speaking of the composition of organic beings I adverted to the manner in which they resist the decomposing effects of chemical agents, and how the seed and egg are capable of being converted into complex living beings, or the whole animal and vegetable kingdom of being resolved into their ultimate elements, by the action of heat, air, and moisture. The same structure remains in either case when life is suddenly destroyed, and the exact difference which arises in the two cases, from the influence of the same causes, can be owing only to the presence of peculiar powers in one case which have disappeared in the other. The cessation of the phenomena of life is the consequence of death; and, there is nothing to die (certainly not the forces of chemistry) but the principle of life upon which the phenomena depended, and which held the elements of structure in vital union (§ 584, 633).

175, a. As set forth in the Medical and Physiological Commentaries, "I believe the vital principle, vital power, organic force, organic power, are one substance, whether material or immaterial; and they refer, with me, to a universal cause of animal and vegetable life, or, rather, as constituting life itself. I believe, also, that this principle has various attributes, common or generic, and partial or specific; or perhaps I should call the former distinct properties. Thus, of the generic, we have irritability, mobility, sensibility, &c., and the modifications of

each of these in the same or different tissues form the specific or partial variations. These properties are also constantly varied in disease, and these variations I call changes in kind. The partial modifi cations in their natural state I designate as variations in kind" (§ 133

163, 171).

175, b. The vital principle has certain analogies with the mind or soul, and with the instinct of animals (§ 241). Each is inherent in organic matter, and the operations of each are through the medium of that matter. Each, respectively, is one substance, and each possesses certain distinct attributes or properties. Each is not only capable of acting by means of organized structure, but of being acted upon, and modified in its nature, and only so in conjunction with that structure

(§ 189, 191, 234 f, 241, 566–568).

Even in the inorganic world we meet with a substance which is not without its light in the way of analogy. This substance is light itself. It is apparently one homogeneous, imponderable, substance, yet said to consist of distinct component parts, each of which is endowed with specific attributes. These component parts would thus be distinct entities, which I do not recognize in relation to the properties of the vital principle, or of the soul. But the distinction is not important to my present purpose, and I should also add that it is indifferent whether we here regard the corpuscular or the more probable wave theory of light (§ 234 e), as the individuality operates in either case.

175, bb. It has been well said by Professor Draper, that

"Just in the same way that I am willing to admit the existence of forty different simple metals, so, upon similar evidence, I am free to admit the existence of fifty different imponderable agents, if need be Is there any thing which should lead us to suppose that the imponderables are constituted by Nature on a plan that is elaborately simple, and the ponderables on one that is elaborately complex? That the former are all modifications of one primordial ether, and the latter intrinsically different bodies, more than a quarter of a hundred of which have been discovered during the present century?" (§ 1085).

"We are thus forced to admit that rays of light, rays of heat, tithonic rays, phosphoric rays, and probably many other radiant forms, have an INDEPENDENT EXISTENCE, and that they can be separated, by proper processes, from each other."—DRAPER'S Treatise on the For-

ces which produce the Organization of Plants, p. 70, 71.

Organic life, however, needs only a single principle, or "imponderable," till it be shown that its supposed properties are individual ex-

istences (\S 165, b).

175, c. I have presented in the Commentaries, in the Essays "on the Vital Powers," and "Spontaneous Generation," and my "Notice of Reviews," certain facts which go to the conclusion that the mind or soul is a distinct immaterial substance, and that the instinctive principle of animals is equally a distinct substance from the brain. I will now add a few words, physiologically, in respect to the main argument of the materialists, drawn from analogy, that the mind, like the gastric juice, the urine, &c., is only a product of the functions of the brain (\S 1076, c).

The analogy is fictitious. Both the mind and instinct are entirely wanting in every known attribute of the product of other organs, and are sui generis in all their characteristics. This is sufficiently obvi-

ous. But there are other considerations which establish the distinction more fully, though they appear not to have engaged the attention of physiologists. What, for example, is the efficient cause of the production of bile, urine, &c.? Certainly the blood, in connection with organic structure and organic actions, and while these actions go on, bile, urine, &c., are uninterruptedly secreted; or, if arrested, it is from the failure of the organic processes. But, it is just otherwise in respect to the mind and the instinctive principle. These are completely suspended in all their manifestations during sleep, and often so with great instantaneousness. And yet there is every reason to believe that the organic functions of the brain continue to move on as perfectly as those of the liver, the kidneys, &c.; especially when it is considered that sleep may happen in almost the twinkling of an eye. Indeed, were any change to befall the brain, it should be more or less manifested by some consequent modification of all the organic actions; particularly as those of animal life undergo complete suspension.

Again, other peculiarities which contradistinguish the mind and instinct from every organic product are the quick transitions from sleeping to waking, and the occurrence of the change without any change in the organic functions of the brain. Take in connection the act of sleeping and the act of waking,—the instant suspension and the instant reproduction of the intellectual operations, and in all their isolated aspects, and the most obtuse understanding must concede not only the entire want of analogy with any other phenomena of nature, but that there must be a unique cause for such perfectly unique effects.

But, again, suppose some change in the organic condition of the brain as the cause of sleep; what is it, I say, that so instantly reinstates its functions when we pass from the sleeping to the waking state? What rouses the organ to its wonted secretion of mind? Are there any analogies supplied by the liver, the kidneys, &c. (§ 241)? What is it, I say, that brings the great nervous centre into operation in all the acts of volition, in all the acts of intellection? This question must be answered consistently, or in some conformity with the argument drawn from analogy. If that can be done, then it must be conceded that the analogy is forcible, and that the argument in favor of materialism is logically taken. So, on the other hand, should the argument fail in this indispensable requisite, materialism must stand convicted of sophistry, insincerity, and a leaning to infidelity (§ 14, c).

The premises are perfectly simple. They are also sound so far as it respects all organic actions and results. The blood, as with all other organs, is the natural stimulus of the brain, and here as there all the organic phenomena are distinctly pronounced. They proceed, in all parts, with uniformity, and without interruption. Nothing can suspend them or modify them in the brain, or elsewhere, during their natural condition. So far the analogy is complete. Now, as it cannot be the blood, according to the analogy, which rouses the brain to action in willing, reflecting, &c., I ask the materialist the nature of the stimulus which operates upon the brain in eliciting the phenomena of mind? And again, I say, if he can sustain his answer by analogy, such is the consistency of Nature in organic philosophy, such the harmony of Design, that it might be difficult to oppose Revelation itself to what is so fundamental in Nature. (Continued at p. 882, § 1076).

175, d. It is assumed by many late physiologists, as Drs. Carpen

ter, Prichard, &c., after admitting and denying the existence of vital properties, and contending for their existence in the elements of matter, and the organizing agency of the forces of chemistry, that, nevertheless, all the results of organic beings are owing to the immediate acts of the Almighty (§ 64, h). This, therefore, as with the author of the "Vestiges of Creation," is only a circuitous method of confounding nature with God (§ $350\frac{3}{4}$ $h-350\frac{3}{4}$ l). Let us, however, suppose that there is a Supreme Being in their opinion, who is the Author of nature, and that He is the Power who presides in organic beings, and regulates all their processes, and we shall see that the doctrine abounds with absurdities. Its advocates generally carry this sophistry so far as to affirm that the particles of matter are constantly maintained in union by Almighty Power, that chemical affinities are nothing but manifestations of that Power, that gravitation is only a constant emanation of the Deity, that digestion, circulation, secretion, excretion, &c., are only immediate acts of God. It is plain, therefore, that they can allow no other God than nature.

But, let us now look physiologically at this pantheism. Organic beings are made up of matter, which, it will be conceded, is distinct from God, if we allow his existence as distinct from matter. It is therefore perfectly consistent to suppose that this matter is endowed with distinct forces for its own government (§ 14, c). If we regard, next, the results of vital stimuli, we have a palpable proof that they elicit actions and physical results through principles which possess the power of acting, or we must take up the absurdity of supposing that they act on God himself. The same may be affirmed of the poisons, medicinal agents, &c. But this will not hold either in religion or philosophy. Nevertheless, it is evident that some active agent is operated upon. If stimulants are applied to the nose, the heart may be thrown, on the instant, into increased action. Of course, it cannot be entertained that God is the agent acted upon in such a case, any more than when prussic acid destroys life with the same instantaneousness: and, therefore, He cannot be assumed as the cause of the healthy and natural functions (64 h, 241 d, $350\frac{3}{4}$ g- $350\frac{3}{4}$ o, $376\frac{1}{2}$, 733 d).

In my "Exam. of Reviews" (in Comm., vol. iii.) I have shown that the doctrine of "the properties of life in the elements of matter" is thoroughly material as it respects the soul (§ 14 c, 189 b, 350\frac{3}{c} l, m).

176. Besides an organized substratum and a principle of life, there is something still beyond not less important to all the great purposes of life. This consists of the actions and various results of life. If all animated beings existed in the state of the seed and ovum, the whole universe would be nearly without any other apparent animation than what is elicited by the forces of physics and chemistry. The movements of the heavenly bodies would be the principal demonstrative source of power.

Although, therefore, the actions and phenomena of organic beings, like the motions of the heavenly orbs, are merely the effects of a peculiar power which we call life, they are, nevertheless, the only attendants of life that interest our senses beyond the physical structure. Hence, it is not remarkable, considering how liable the senses are to take the lead of the understanding, that even the soundest minds have supposed that life consists of its results alone, and have overlooked the great efficient cause or power upon which the results

depend (§ 234 g, 247). Had they considered for a moment, however, the analogy which subsists between the motions of organic beings and those of the heavenly orbs, and that the latter depend upon a power which is called gravitation, and without which all the orbs would suffer the stillness of death, the conclusion would have been unavoidable that celestial motion is merely an effect, and, therefore, that all organic motions and their results depend upon moving powers. They should have seen, too, that when a drop of prussic acid, or of the spirituous extract of nux vomica, is applied to the tongue, all the phenomena of life are instantly extinguished, that nothing can reproduce them although the organized structure remains unimpaired, and that the whole being is immediately resolved into its ultimate elements (§ 1042).

177. The properties of life are the fundamental cause of all healthy and morbid phenomena. They are liable to be more or less diverted from their natural state by a variety of causes, and these new conditions constitute the most essential part of disease. This instability of the properties of life is at the foundation of all disease, and even of therapeutics (§ 642, b). Other causes, acting upon these morbid conditions, alter them in yet other ways, and contribute to their restoration to the natural standard. This is the aim of all our remedies; and the recuperative tendency of the properties of life (the ris medicatrix natura), when they are driven by morbific causes from their healthy state, enables them to recover spontaneously from the artificial conditions which are substituted by remedial agents for the more intensely morbid (§ 172, 851 a, 853, 854, 893, 900, 901, 905, 1059).

178. Notwithstanding the natural instability of the properties of life, they have a definite character in every part of the body, according to the nature of each part, at every hour of existence (§ 153-156).

179. The exact nature of disease depends mostly upon the foregoing definite conditions (§ 178), and upon the particular virtues of the morbific agents. The salutary changes produced by remedial agents involve the same principles. But, these definite changes, and the action of morbific and remedial agents, are liable to contingent influences from habits, &c.; as set forth under the fifth division of Physiology. Our calculation of results is thus embarrassed according to the nature and extent of the contingent influences (§ 756, b).

180. The vital properties are without renovation, or mutation in health, except as they are liable to certain natural modifications at different periods of life, or during gestation, or from the slow operation of external agents, as in the artificial temperaments. They must remain without renewal, to be forever ready for the work of nutri-

tion, &c. (§ 237, 570–630).

181. The permanency of the vital properties enables us to understand the nature of predisposition to disease, artificial temperaments, and hereditary diseases, which many refer to the ever-changing blood (§ 238, 666).

182, a. According as the vital properties may be modified, either in the foregoing manner (§ 181), or as in disease (§ 177), so will be the condition of the elementary combinations, and other physical products.

182, b. Nevertheless, the properties of life never undergo any radical change till they shall have passed the limit of their recuperative

power (§ 177), and are therefore approaching a state of extinction. Hence, essentially, in connection with the nature of the remote causes,

the analogies among diseases (§ 670, 756).

183. In their highest development, the properties of the vital principle are six; namely, irritability, mobility, vital affinity, vivification, sensibility, and the nervous power (§ 175). They are called vital properties, vital powers, and vital forces; but are clearly attributes of a common principle, just as judgment, perception, the will, &c., are properties of the soul. They will be examined according to their nearest relations to each other in the most perfect beings, and their practical application.

184, a. The first four properties (§ 183) are common to plants and animals, and reside in all the tissues. They may be properly called *organic* properties, as they carry on the organic processes (§ 476-492, 516 a). The last two are peculiar to animals. This multiplication of vital properties in the animal kingdom harmonizes with the introduction of tissues and organs which have no existence in plants (§ 201,

222, 232, 450, &c., 500).

184, b. The nervous power has been considered a principle by itself, and often regarded by eminent physiologists as the galvanic fluid, generated by the brain, or other organs, and conducted by the nerves (Med. and Phys. Comm., vol. i., p. 65-68, 107-119). Its phenomena, however, declare it to be entirely distinct in its nature from all things else; while its analogies to the other properties of life show it to be an element of the vital principle (§ 227-232). If it be difficult for the limited comprehension of man to surmise how this property should prove an agent to others with which it is associated, the difficulty is no greater than the admitted fact that the will may control other properties of the mind, and the passions. Nevertheless, it is unimportant in a practical sense, and in the institution of principles, whether the nervous power be considered a property of the vital principle, or a principle by itself (§ 175 bb, 186, 226, 1072 b).

185. Although the organic properties which are common to plants and animals are essentially the same, they possess greater modifications throughout than will have been seen to appertain to the same properties in the different parts of animals. But all the variations in the two organic kingdoms are intimately connected by close analogies; just as they are in the different animal tissues (§ 133, &c.). Much of the difference in the general vital constitution of the two kingdoms is owing to the presence in one, and the absence in the other, of the nervous system, and those corresponding properties which play so important a part in the animal tribes (§ 733, f). In both departments of organic nature, however, there is, essentially, the same principle of life, its great organic elements, and the same great functions over which they preside. Here, too, in the vegetable kingdom. in the modifications of structure and of the organic properties and functions, and of the laws which they obey, we witness the greatest simplification of life. The vegetable tribes, being also exempt from most of those secondary influences which so constantly embarrass our inquiries in more complex organization, especially from the complications that arise from nervous influence, are better subjects for the experimental researches which concern the philosophy of life; and the facts, therefore, which they supply may be carried up, for the same general purpose, as sound analogies, to more complex beings

(§ 191 a, 409, 733, 853, 1052).

186. The mental property, perception, is necessary to the exercise of specific and common sensibility, and the will to that of mobility as modified in the function of voluntary motion (§ 194, &c., 226, 241 243, 500 e). Here we have not only other analogies between the intellectual and vital principles, but each is brought into direct action with the other (§ 175, 184 b).

187. The vital properties co-operate together in their functions.

more or less, as they exist in any given being.

187½. The conditions now mentioned as to the principle of life, as well as all those to be hereafter stated, and the phenomena of which they are predicated, form other groups of facts, which, individually and collectively, contradistinguish the principle of life from all the forces of inorganic nature (§ 1041).

IRRITABILITY.

188, a. Irritability belongs to all tissues, and is the property upon which all vital agents, external and internal, physical and mental, natural, morbific, and remedial, produce impressions in organic life; except as sensibility is concerned in reflex nervous actions (§ 201–203, 226), and as the nerves, from being incorporated in other tissues, take a subordinate part in organic functions, independently of reflex action (§ 461, 492). All actions or motions, in animal as well as organic life, are brought about by impressions on irritability (§ 205, 233, 257, 486, 500 d). This may be either by the direct action of the agent, or

by the indirect action of the nervous power (§ 222, &c.).

When vital agents affect the organic functions in a direct manner, it is by direct action upon the irritability of the parts which perform the functions. This is true, in part, of the natural excitants of organs; as blood acts directly upon the irritability of the heart and blood-vessels, bile upon that of the intestines, food upon that of the stomach, &c. In these cases, however, influences are also transmitted through sympathetic sensibility to the nervous centres, and thence reflected upon the muscular tissue of the organs (§ 201, 514 f). So, also, remedial agents operate upon the irritability of parts to which they are applied, and thus affect their functions in a direct manner. But their influences are commonly more extensive, and then they call into operation the nervous power by their action upon sensibility (§ 201), thus giving rise to reflex nervous actions (§ 222, &c., $475\frac{1}{2}$, 500).

When mental emotions affect the organic functions it is by determining the nervous power upon the irritability of the parts (§ 226, 227). And, although sensibility receives the primary impressions in the function of sympathy, the resulting influences upon organic actions are brought about by a determination of the nervous power upon the irritability of the affected organs (§ 201, 226, 227, 475½, 647½, 1041).

188, b. When vital agents act upon specific sensibility the results of their impressions are merely their propagation to the nervous centres, and a consequent action upon those parts (§ 194-204, 222-234).

188, c. I shall endeavor to show that the doctrine is entirely unfounded which supposes that vital agents produce their effects in organic life by direct impressions upon the nervous system, excepting so far as explained above (§ 188 a). This demonstration, indeed, was made in

the Commentaries, but mainly by other processes than will be presented in the Institutes. The fact alone, however, should be adequate, that plants have no nervous system, yet carry on all the essential organic processes that exist in animals; while they are alike liable to corresponding results from the operation of morbific and remedial agents.

188½, a. Every thing which is capable of affecting irritability, and sensibility, is a vital agent. These agents are either natural to the body, as blood, heat, bile, &c., or external, as food, air, heat, light, electricity, &c. Irritability is perpetually alive to the stimulus of blood in all parts of the sanguiferous system, as it is to that of the sap wherever it circulates (§ 136). This shows the exquisite suscep-

tibility of the property.

185½, b. Many vital agents, those just mentioned, are indispensable to the maintenance of organic processes, either in animals or plants. Hence, from maintaining the organic powers in constant action, they are called vital stimuli. Those of a morbific or remedial nature are known by these epithets, though, in a philosophical sense, they are vital agents. They are distinguished by very different characteristics from the natural agents of life; even all those which are stimulant to the organic processes; for they not only excite the properties of life, but are capable, also, of affecting their intrinsic nature. But, there are others, whose effect, in certain degrees of intensity, is directly the reverse of the foregoing, as hydrocyanic acid, tobacco, &c.; and these, when thus operating, are vital depressants (§ 441 d, 650, 743).

188½, c. Some of the vital stimuli which are natural to the body, as blood, and bile, and also food, subserve other purposes than that alone of rousing the action of organs. They are also acted upon and appropriated to the uses of the system. This is more extensively true of animals than of plants. In the latter case there are certain external stimuli which are indispensable to vegetation, and whose only operation is that of excitants, but which are comparatively unimportant to animals. These agents are particularly light and heat, and perhaps electricity. The heat which is most important to animals

is generated by the living organism.

188½, d. An important error has prevailed among chemists, from their necessary want of physiological knowledge, in regarding the imponderable agents as the causes of life, and not as mere stimuli to those real causes which are implanted in the organization itself, and by which, of course, all the actions and results are determined. This vitiation of philosophy has beset, especially, the functions of animals as it regards their assumed dependence on electricity, and the functions of plants in their obvious dependence upon light. The fallacy of the former hypothesis is shown extensively in the Medical and Physiological Commentaries (Essay on the Vital Powers and its Appendix). Of the latter I will now say, that in all the relations of light to plants we have the most distinct analogies with other vital stimuli to guide us to the same certain conclusion, that, like other stimuli, it does but rouse the properties of life to certain special modes of action, by which they decompose carbonic acid gas, carry on the work of appropriation, &c. (Parallel Columns, nos. 64, 65, 66, 68, 74).*

But, thanks to my colleague, Professor Draper, whose name in early life glows upon the sunbeam, organic science is supplied with

* See Correlation of Forces, p. 921, § 1085.

an adornment which vies in delicacy, yet sublimity, with the capa-

bilities of the nervous power (§ 222, &c., 234 e).

The professor has obligingly furnished me with the following statement of the progress, and nature, of the discoveries in relation to the solar beam. Thus:

"Until the time of Sir Isaac Newton, it was universally supposed that light was a simple elementary body, and therefore incapable of

decomposition.

"The great optical discovery of Newton consisted in proving that the white light of the sun, or of day, is in reality made up of many colored varieties. He fixed the number at seven: red, orange, yellow, green, blue, indigo, violet. He indisputably established that that which we commonly call light is made up of, and therefore con tains, the seven prismatic rays. They differ not only by impressing the organ of vision with different sensations, but also in intrinsic brilliancy or illuminating power. It is to be remarked that of these the

yellow is the brightest.

"It was the opinion of Newton, and his followers, that when light falls upon bodies and disappears, it is converted into heat; or, in other words, that heat is extinguished light. Sir W. Herschel, the astronomer, proved the separate and distinct nature of these principles. The proof chiefly depends on the fact that the brightest ray is not the hottest, and that in the sunbeams there exist rays in abundance which are wholly invisible, but which can rapidly raise a thermometer. That which we cannot see we should scarcely call light. Moreover, a vessel of hot water in the darkest place is invisible; yet common observation shows it is emitting calorific emanations. The independence of light and heat may therefore be considered as established.

"Some of the alchemists discovered that certain of the white salts of silver (the chloride) turned black under the influence of the sunshine. Toward the close of the last century it was shown that the rays which produced this effect were invisible, and therefore could not be regarded as rays of light. At a later period I showed that they could not disturb a thermometer, or communicate to our organs the impression of warmth, and therefore must be distinct from heat. From the circumstance that they are always accompanied by light, I gave them the provisional name of *Tithonic* rays, from the fable of

Tithonus and Aurora.

"The same species of modification which light exhibits (as colors) has been traced by Melloni for the rays of heat, and by me for the Tithonic rays. But, as both these classes of rays are invisible, their coloration must be necessarily so too, and is known to us only by indirect facts. We speak of it, therefore, as ideal or imaginary. There are seven colors for heat and the chemical rays, as there are seven for light.

"It is worth remarking how complex the constitution of light is now understood to be, when contrasted with the opinion held by the

predecessors of Newton (§ 183, &c.).

"I have established, as respects some of these rays, that they discharge extraordinary functions. It is the *yellow* ray of light which has control of the evolution of plants. Under its influence their leaves effect the decomposition of carbonic acid gas in the atmosphere, setting free its oxygen and fixing its carbon. This wonderful phenom-

enon is unquestionably the first step in the production of organized matter, such as starch, woody fibre, &c., from inorganic gases. The carbon is first fixed under the form of chlorophyll in the leaf. Chlorophyll occurs under remarkable circumstances as the coloring matter of bile.

"Extended investigations have shown that each particular ray of these principles exerts specific powers. The compounds in which silver enters are affected by those of a violet color; chlorine is most acted on by the indigo; and carbon by the yellow. It is for this reason, as I have shown, that to the animal eye the yellow ray is brightest. If nature could have formed a retina of which silver was the basis, the indigo would have been the most brilliant ray. All our conceptions of beauty in colors depend, therefore, on the physical peculiarities of the carbon atom. And it is a beautiful and interesting fact, that the ray which evokes from atmospheric air the multitude of forms composing the vegetable world has charge of the process of vision in all animals (p. 797, 798, § 1034).

"Dr. Gardner discovered that the movements of plants are chiefly directed by the indigo rays of light. They grow in the direction in which it falls upon them; and the blue color of the sky is one of the

causes of the upright growth of stems.

"Besides the three classes of rays which I have mentioned, there is a fourth, of which much less is known; the phosphorogenic rays. These take their name from the fact that when they fall on certain bodies, such as the diamond, Canton's phosphorus, &c., they cause them to glow with a pale or splendid light. The extraordinary pecu-

liarity they possess is, that glass is opaque to them.

"The advance of chemical optics has sufficiently proved that each of the constituent rays of the sunbeam, or of light derived from artificial sources, has capabilities of its own. Thus, each of the seven rays of light impresses our minds with special sensations. The yellow, moreover, controls the growth of plants, the indigo their movements. Of the Tithonic rays, the blue is the one concerned in Daguerreotype portrait taking, and the red can bleach paper blacked with oxide of silver. The same peculiarities will undoubtedly be discovered as respects the rays of heat."

Professor Draper's analysis of the sunbeam, by subjecting plants to the various elements of the solar spectrum, demonstrates, what was still conjectural, the individuality of its component parts, and establishes their rank as distinct physical and vital agents. Analogy justified this demonstration; and had the professor proceeded upon the basis of analogy, and applied the spectrum to the philosophy of life, it would have been one of the most splendid achievements of the human mind. But, like Philip and Müller, in respect to the nervous power, he lost the opportunity; but in losing it, he reared another beacon upon the quicksands of chemistry (§ 476, 493, 514½ b).

The chemical properties of the solar spectrum having been announced by other philosophers, it only remained to infer that, like all other things, the integral parts of the spectrum which had manifested peculiar agencies in the physical world would probably, if each were specifically distinct, exhibit greater diversities in organic life (§ 52, 136, 175 bb). This would appear to settle the individuality of the numerous rays. The results of sensation, the test of the thermometer, and even

of chemistry, with their united force, established only probabilities. Nature may have supplied the unerring, the "indisputable" requisite, in the Vital Principle. And, although discovery is probably only begun, the principles of individuality, and of organic relations, are as well determined by the properties of one ray as by those of a dozen. That others than such as are known belong to the class of vital agents, there can be little doubt. The physical capabilities of other rays supply a strong analogy for this conclusion. But the doctrine of individuality is unimportant to our purpose, since, if the homogeneous nature of light and the elegant wave theory become established, each prismatic ray will be as much distinguished by peculiar properties as if every ray were an entity (§ 175 bb, 234 e).

It will be now observed that every tangible substance yields an overwhelming analogy in corroboration of the doctrine which I advance as to the vital relations of the solar spectrum; while the coincidence in the specific influences of its component parts upon organic life with every other distinct agent, equally in its own turn, surrounds

the spectrum with a vital philosophy.

Nor is this alone the importance to organic philosophy of the rich discovery. The individual parts of the spectrum not only affect sensibility and irritability in modes peculiar to each, but, in beautiful harmony with all tangible substances, each part, respectively, affects certain organs only, according to their special modifications of irritability or sensibility, and according to its own peculiar virtues (\S 133 b, 136, 137 b, 150 a, 188 a, 190, 194, 199, 203). Here, also, it will be seen, is another analogical proof of the vital nature of the influences

of light upon organic beings (§ 74 a, 303 e).

Much, also, may be found in Professor Draper's own conclusions to show the vital nature of the agency of light. Take, for example, the statement that the "indigo ray controls the movements of plants," and that "the blue color of the sky is one of the causes of the upright growth of plants." Now what intelligible explanation can chemistry offer of those phenomena in their undoubted relation to light? The unavoidable answer supplies an indisputable analogy for the vital influences of the yellow ray, &c. As to the decomposition of carbonic acid gas, it is the only phenomenon in organic life, and I may add animal, which Liebig abstracted, unequivocally, from chemical agen-

cies (§ 350, nos. 66, 68).

If we now carry the foregoing analogies along in comparing the effects of heat and electricity with those of light upon vegetable organization, we shall readily see that a common philosophy attends the operation of the whole, and that light, in its relation to vegetable life, is nothing but a vital stimulus, adapted to the peculiarly modified vital properties of the leaf, as blood is to the sanguiferous system, sap to the circulatory system of plants, bile to the intestine, semen to the ovum, pollen to the germen, &c. (§ 133, &c.). Consider, too, the analogy which is supplied, in the foregoing aspect, by the action of light upon the retina (§ 234, e), and how it contributes to the production of various hues of the skin, and how, on the other hand, the skin becomes blanched, like the plant, by the exclusion of light. And the analogy may be extended to the motions produced in the iris by the action of light upon the "carbon atom" of the retina (§ 514, k). Nay, more, the action of light, as I have shown, by its absence, at

least, reaches far beyond the peculiarly modified sensibility of the retina (§ 199); since, by its long privation, the entire organ of vision ceases to be developed (§ 74). Again, by what chemical philosophy shall we interpret not only the painful effect of light upon an inflamed eye, but its aggravation of the disease? And here, by-the-way, its simultaneous action upon the sensibility of animal life and the irri-

tability of organic life concur together in the demonstration.

And now to continue the analogies with electricity and galvanism. Either will promote the growth of plants which no degree or modification of light can exert. So will they, also, promote nutrition in muscles that are wasted in paralysis; and if the pneumogastric nerve be divided, the transmission of galvanism through the inferior portion will rouse the stomach to the production of the true gastric juice and partially restore digestion. And here I may stop to say, that the coincidence in the effects of galvanism upon vegetable and animal organization is one of the many facts which establish the general identity of the properties of life in both departments of the animated kingdom, while it proves that galvanism and the nervous power are perfectly distinct, though each be a vital agent (§ 73 b, 74, 185, 226). Again, also, galvanism is a remedial agent, affecting morbid functions after the manner of other remedies, which, with its analogy to light in promoting the growth of plants, shows farther that the latter is, in the same sense, only a peculiar stimulus to organic functions (§ 74, 303).

What is said by Professor Draper in the foregoing abstract on the subject of the yellow ray in its connection with sensation deserves a critical inquiry, not only for the sake of the facts, but as contributing light upon organic philosophy. The chemical doctrine of vision is so clearly fallacious, that any specific relations which may be shown between particular rays of light and the sensibility of the retina, may advance our knowledge, analogically, of the connection of the rays with organic functions, through irritability. But I see not how it is shown that the yellow ray "has charge of the process of vision in all animals," since "each of the seven rays of light impresses our minds

with special sensations" (p. 797-798, § 1034).

Moreover, if the yellow ray give rise to sensation by its action on the carbon atom, or by any chemical influence, then, also, do each of the remaining six, and each one in modes peculiar to itself, and in all the cases upon distinct bases. Nay, more, when the retina feels the united rays, each of the seven must simultaneously exert their specific chemical actions. Besides, how are those invisible rays employed which operate chemically upon inorganic compounds? What means the important distinction between the visible and invisible rays that the former act upon organic beings, the latter upon inorganic?

From the close analogies between the relation of physical agents to sensibility in animal life and irritability in organic life, if their action in the former case be not chemical, but vital, so is it equally in the latter, and vice versa. It is either vital throughout, or chemical altogether.

But, organic philosophy, through its analogies, should be able to explain what chemistry cannot as to the resulting sensation when the united rays of the sunbeam fall upon the retina. One example will do it. Thus, every distinct agent of positive virtues produces distinct impressions in organic life. But, by uniting two or more together, either mechanically or chemically, a new agent is created, which op-

erates either in an individual sense, or if by several virtues, as an entire whole. So, in respect to vision, the united virtues of the numerous rays of the sunbeam acting upon the sensibility of the retina give rise to sensation attended by a white light (\S 136, 188, 193, 199, 650, 872 a, 1054). In organic life they equally act separately or unitedly.

The intelligent reader may now test the foregoing philosophy by what is perpetually observed within himself, and bring to its illustration the exact analogies which I have indicated as being supplied by the different passions of the mind; how anger stimulates the whole vascular system,—how fear depresses it,—how shame acts upon the capillaries of the face alone, -how joy acts upon the heart and kindles the eyes in its own peculiar way, or its antagonist, grief, seeks the lachrymal gland, or expectation of food the parotids,-how fear, again. rouses the kidneys, or bathes the skin with perspiration,-how love poises its aim at the genital organs (§ 227, 234 g, 509, 512, &c.). If, therefore, light do not affect organic actions, and influence organic results as supposed of the foregoing mental causes, and as imputed, also, to all vital agents, but, on the contrary, its operations upon plants, and therefore upon animals, be of a chemical nature, then, by the clearest analogy, all other agents of life, the mind and its passions, every act of intellection, every voluntary movement, belong equally to the

same category (§ 175 c, 349 e, 1072).

189, a. Where physical views of life obtain, their advocates suppose that vital agents operate directly upon the structure. This is one of the first steps in materialism. Many of the chemical school imagine, as Liebig expresses it, that "every motion, every manifestation of force, is the result of a transformation of the structure, or of the substance of parts;" that "every thought, every mental affection, is the result of a change in the composition of the substance of the brain." And so of every pulsation of the heart (§ 350). Others, again, who belong to the school of vitalism, to accommodate their language to the physical conceptions of the day, speak of the action of vital agents "upon the structure through the medium of the vital properties." This difference among vitalists is only verbal; since, by admission, the structure can only be affected "through the medium of its vital properties," upon which, therefore, the impression must be made. Hence, distinguished vitalists, Professor Caldwell, for example, who defend the semi-physical mode of expression, often fall into the simple realities of their philosophy. Thus the professor, in his "Outlines of a Course of Lectures," observes that "irritability and sensibility can be acted on by stimulants alone." "Purgative medicines act chiefly on our irritability," &c. (p. 185, 187). And so it ever happens with inquirers after truth. They cannot adhere even to ambiguities of language; and others who see the truth, but build upon hypotheses, are often betrayed into fatal contradictions (§ 64, 236, 345-350, $350\frac{3}{4}$ n, 699 c, 740, 819 b).

189, b. But, what is more remarkable, the most absolute physical philosophers of life, they who deride the existence of the "vital properties," and speak of their "destruction" as an absurdity, not only fall into the language of the vitalists, but unavoidably contradict their whole system of materialism, whenever they approach the realities of life. This is true even of Dr. Carpenter, who, in his review of my Commentaries attempted their overthrow by satirizing the supposed exist-

ence of "vital properties," and particularly the supposition that prop erties could be "destroyed." Thus, then, Dr. Carpenter, at a subsequent time, and in a work of great professional popularity. The capitals and italics are mine:

"It is a fact of some importance, in relation to the disputed question of the connection of muscular irritability with the nervous system, that when, by the application of narcotic substances to the nerves, their VITAL PROPERTIES ARE DESTROYED, the irritability of the muscle may remain for some time longer; and the latter must, therefore, be independent of the former. Hence we should conclude that contractility [mobility, of these Institutes, § 205] must be a property really inherent in muscular tissue, which MAY BE CALLED INTO ACTION by various stimuli Applied to itself, and which may be weakened by various depressing agents APPLIED TO ITSELF; and that the nerves have the power of conveying the stimuli which CALL THE PROPERTY INTO ACTION, but have little or no other influence on IT."—CARPENTER'S Human Physiology, Section 376.—See, also, this work, § 175 d, 167 d, 291, 3503 b; and Examination of Reviews, p. 8-12, 26-43.

It is important to the great objects of medicine, that I should now say, that the foregoing is only an example of numerous palpable contradictions of the physical views which form the fundamental philosophy of life in the foregoing work, and, I may add, of most others which are devoted to the propagation of medical materialism. It will be seen that enough is admitted in the preceding quotation to substantiate every doctrine advanced in these Institutes. There are the vital properties, in all their individuality, called into action by stimuli, and "acting" of themselves even beyond the doctrine of vitalists, or, again, "weakened by various depressing agents," and liable to be "destroyed;" though I do not allow, as affirmed in the quotation, that "contractility" is the property acted upon (§ 206). Finally, we have admitted, "that the nerves have the power of conveying the stimuli which call the property [contractility, or mobility] into action;" and which is all that is necessary to the whole doctrine which I have propounded as to the nervous power ($\S 222-233\frac{3}{4}$, 500, &c., 512, &c., \$93-905).

189, c. The impressions which are made on the vital properties be come the causation of the changes which may ensue in the actions, or structure, of the solids, where the impression is made. No vital agents elicit actions, or a single phenomenon of life, when applied to an inorganic compound, not even from an organic being just dead from instant destruction by hydrocyanic acid, or by a pin thrust into the medulla oblongata. On the contrary, indeed, all the agents which had before contributed to the maintenance of life, now carry out the work of destruction, and more speedily resolve the organic fabric into its ultimate elements than any inorganic compound (§ 62). It follows, therefore, that agents do not elicit the actions of life by operating upon the organized structure; but upon those properties which hydrocyanic acid, &c., may extinguish in an instant of time; nor do they operate upon the functions, since those are merely effects (§ 176). And is it not a greater paradox that hydrocyanic acid, or aconite, &c., should destroy life in a second of time by its action upon the mere structure than upon that living principle which imparts to the organic kingdom all its peculiar characteristics? Or, as the blood, or joy, or anger, rouses the heart, or as fear brings on perspiration, micturition, &c., or as the want of air throws into action the respiratory muscles,

or as odors, light, &c., produce their sensations?

By facts of the foregoing nature, and by all those considerations which have been made in relation to the differences in the vital constitution of the different tissues, and of different parts of one and the same continuous tissue (as of the alimentary and pulmonary mucous membrane, § 133, &c.), it becomes perfectly obvious that the properties of life are something per se, something besides organization itself, or organic functions, and upon which the agents of life exert their immediate impressions (§ 1029, 1030, 1034, 1041).

There can, therefore, be no appreciation of the laws of organic be ings, of the modus operandi of natural, morbific, or remedial agents, of healthy or morbid processes, of voluntary or involuntary muscular motion, of the results of the operation of the nervous power and sensibility, or even of perception, without a critical reference to the properties of life as the efficient causes, and as receiving the impressions which may be exerted by external and internal agents (§ 872).

190, a. Irritability, and other vital properties, are naturally modified, in kind and degree, in the different tissues, in tissues of the same order, and in different parts of one and the same continuous tissue

(§ 133, &c., 199, 203, 227-232, 525-529).

These natural modifications are shown in all parts by the peculiar action of the natural stimuli of life; as blood upon the heart and blood-vessels, food on the stomach, bile on the intestines, urine on the bladder, the will, through the nervous power, upon the voluntary muscles (§ 215, 227, 486), and by the differences that arise from their action on parts to which they are not peculiar. And so of the diversi-

fied effects of external agents on different parts.

190, b. There are remarkable modifications of irritability in the ova of oviparous and viviparous animals, and in seeds. Semen is the only natural stimulus of the former, in their absolute state of ova; while in the ova of viviparous animals, the actions, after being roused by the stimulus of semen, must go on to a full development of the organic being, and in undisturbed connection with the parent; but, in the oviparous, when the ovum has acquired a certain development, the actions cease spontaneously, the properties of life no longer obeying the vital stimuli as in the other case. These properties then become dormant (and in the seed, also), and nature, having fulfilled her final cause, the ovum is expelled from the body, and the seed cast off, that they may be subjected to new agents. Semen will not now act upon the egg, but heat and atmospheric air become necessary to restore the actions, and carry out the process originally instituted by the specific stimulus of semen.

There are certain oviparous animals that present other peculiarities, and other changing modifications, of irritability in respect to their ova. At certain seasons their ova undergo a partial development from the influence of season, and from the stimuli supplied by the female parent. These influences, however, finally cease to operate, and the ovum is expelled to undergo the action of semen in the external world. This action again modifies irritability, and adapts it to other

vital stimuli.

Again, it may be affirmed of many oviparous animals, e.g. birds, that a partial development of the ovum takes place, though imperfectly,

through stimuli supplied by the female parent, and the ovum is ultimately expelled as when incipient development is brought about by the stimulus of semen, but that these ova are insusceptible of renewed actions, either from the stimulus of semen, or other vital agents (§

71-73, 1051).

191, a. The variations in kind and degree of irritability (§ 190) adapt each part to be acted upon by peculiar natural agents, while the same agents may have a pernicious effect on other parts, in the great plan of organic life (§ 133, &c.). The same principle governs the operation of morbific, and, more or less, of remedial agents, and is one of the main causes of disease, and of the determination of disease upon one part in preference to another (§ 149–151). The principle is, therefore, very comprehensive, and refers as well to the kind, energy, and degree of the operating causes or agents, as to the kind and degree of irritability (§ 150). And so, also, of sensibility (§ 194).

The principle is not only seen in all parts of the organic being, but every distinct species of animal and plant has, in a collective sense, its own special modification of irritability, through which its organic habits as to food, composition, nutrition, &c., are specifically regulated. It is this which renders what is poisonous to one animal or plant salubrious or inoffensive to another. And this lets us into a knowledge of the reason why certain atmospheric influences induce the "milk-sickness" in the kinc of the Western States, and probably in no other animal. It reveals to us how it is that the stately platanus occidentalis and the common peach tree have been dying out over extensive regions of country, and why the potato-crop is cut off, year after year, in vast regions of Europe and America, while every other tree and herb escape the epidemics (§ 150). These very facts demonstrate, also, the principle as to the natural modifications of the properties of life, and establish, alone, the fundamental identity of the vital properties in the two departments of the organic kingdom (§ 185).

191, b. Again, more remarkable modifications of irritability, or changes in kind, are artificially effected by morbific and remedial influences, external and internal, physical and moral; and these, far more than a mere increase and depression of this property, constitute an essential part of disease. These affections of irritability give rise to new series of influences, from every variety of agent, and often very different from such as are exerted under circumstances of health (§ 542). Hence it is that ordinary food, &c., becomes morbific in diseased conditions, remedial agents operative, either for good or for evil, when otherwise they might fail of any effect (§ 226), and, upon this mutability, and varying susceptibility of the property now under consideration, is greatly founded the art of medicine. It is, especially, these varying conditions of irritability which demand so much critical reference to the exact nature of remedial agents, their doses, &c. (§ 857, 871, 878), and to the mutability of the property is particularly due the salubrious influences which are exerted (§ 901).

191, c. And here we have striking analogies in the manner in which the properties of the mind are modified in their character and again restored to their integrity when the organic properties of the

brain become affected in the foregoing manner (§ 175).

191, d. Remote analogies probably exist even in the inorganic kingdom; though we have apparently nothing there in this respect

which transcends other affinities between the two great kingdoms of nature. We do not find that dead matter is endowed with properties as specifically distinct from the matter itself as the living being and the properties by which it is governed. And, so far as this analogy extends to dead matter, its properties do not appear to be liable to any mutations in kind, but only in degree; and here it would seem that the analogy should end, since we do not find that instability in the mineral world which, in the organic, grows out of the mutability

of the properties of life.

What I have thus said of the analogies between the properties of living and dead matter is sustained by the late researches of chemists. Thus, on the allotropism of simple bodies, it is said by Prof. Draper, that, "to a certain extent, the views of M. Berzelius coincide with those which have offered themselves to me from the study of the properties of chlorine. They are not, however, altogether the same. M Berzelius infers that elementary bodies can assume, under varying circumstances, different qualities. The idea which it is attempted to communicate in this memoir is simply this,—that a given substance, such as chlorine, can pass from a state of high activity, in which it possesses all its well-known properties, to a state of complete inactivity, in which even its most energetic affinities disappear. And that, between these extremes there are innumerable intermediate points. Between the two views there is, therefore, this essential difference; From the former, it does not appear what the nature of the newly-assumed properties may be; from the latter, they must obviously be of the same character, and differ only in intensity or degree, diminishing from stage to stage until complete inactivity results."-Draper, on Allotropism of Chlorine as Connected with the Theory of Substitutions. 1845.

192. Irritability stands as a sentinel at all the openings and pores of the body, and between the capillary and extreme vessels of the arterial system; admitting and excluding according to its natural modifications in different parts. Thus, all but chyme is excluded from the duodenum by the pyloric orifice of the stomach, and all but atmospheric air by the glottis. The globules of blood are vastly smaller than the visible capillaries which carry only white blood, from which they are excluded by the peculiar irritability of these vessels.* When admitted, as in inflammation, it arises from a morbid alteration of irritability. And so when the lacteals absorb deleterious agents, or the pylorus allows the escape of undigested food. There is no analogy between a set of inert tubes and the living ducts. And yet are we presented with tubular instruments of glass, &c., to demonstrate the laws which govern the circulation of the blood and of sap, and sponges and lamp-wick to exemplify the process of absorption as carried on

by the lymphatics and lacteals (§ 289, 291).

193. Bichat confounded irritability with sensibility, by calling the former organic sensibility, and the latter animal sensibility. He made, also, a greater mistake in supposing that irritability and sensibility are only different degrees of one property. This fact derives its importance from the high authority of the French philosopher, and the errors into which he has thus led a multitude of others.

The coincident functions between plants and animals, and organic actions being carried on in parts of animals after the greatest possible destruction of the nervous communications, evince the clearest distinc-

^{*} A few are said to be admitted, but are visible only through the microscope.

tion between irritability and sensibility, however close their analogies in respect to the operation of physical agents. Nor can the nervous influence act as a stimulus in such cases, though the nerves may form a channel for other stimuli (§ 461, $476\frac{1}{2}c$, 489, 490).

2. SENSIBILITY.

194. Sensibility, which is peculiar to the vital principle of animals, resides exclusively in the nervous system. That which gives rise to true sensation is mainly limited to the cerebro-spinal system (§ 184, 523).

195. Through sensibility we learn the existence and nature of external objects. These objects make their impressions upon this property as we have seen of other agents in respect to irritability (§ 188,

&c.).

Another important function is also performed by sensibility, which consists in the transmission of impressions to the cerebro-spinal axis, as a part of the great function of sympathy, or reflex nervous action.

All the modifications of sensibility are designed for the transmission of impressions from the circumference to the nervous centres (§ 450, 451). The sympathetic nerve contributes centres in organic life.

196. The nerves are the organs of sensibility, and the brain and spinal cord the recipients of impressions transmitted by this property through the medium of the nerves. Perception is also necessary to the recognized modifications of sensation; and, therefore, the perfect exercise of the power, in its function of true sensation, requires a healthy state of the foregoing elements (§ 523, no. 3).

197. Sensibility is said to be of two kinds, common and specific. I shall distinguish it into a third kind, which may be called sympathetic

sensibility (\S 1037, b).

198. Common sensibility is the source of pain, and resides in all the nerves. It is generally dormant in the organs of organic life, but may be greatly roused by disease. The best examples of this latent state occur in the ligaments and bones. Its development by disease is a clear illustration of the light which is reflected upon natural phys-

iological conditions by their morbid changes (§ 137, d).

199. Specific sensibility is peculiar to the senses, where it manifests very striking peculiarities. Light, alone, will affect the specific sensibility of the retina, the intrinsic virtues, only, of various substances give rise to tasting and smelling, certain mechanical impressions to hearing, &c. This proves a difference, or modification, of specific sensibility in the several organs of sense, by which, as in the case of irritability (§ 190, 191), it is adapted, in various parts, to the action of special stimuli, according to the predetermined uses of each part.

199½. The impressions transmitted by common and specific sensibility are received by the brain alone, or its equivalent. The spinal cord is only a medium of communication. These, also, are the kinds of sensibility which require for their operation the exercise of perception (§ 451, 523, nos. 1, 2); and it is these upon which true sensation depends. Whenever brought into operation, the mind takes cognizance of the transmitted impressions (p. 864, note).

strongly pronounced, and are clear examples of what is meant by

200. The foregoing (§ 197-199) are coincident with what we have seen of differences in irritability (§ 133, &c., 190, 191), though more

natural modifications of the vital properties; and illustrate those modifications which constitute the essence of disease (§ 133, &c., 191).

The three principal kinds of sensibility, and the several modifications of the specific kind, as shown by the special causes which, respectively, give rise to seeing, tasting, smelling, &c., also illustrate the principle which governs the special relations of different agents, natural, morbific, and remedial, to irritability as modified in different parts; and this, also, reciprocally illustrates the characteristics of sensibility. A harmony of laws prevails universally (§ 133–138). Like irritability, sensibility is also liable to artificial modifications from the action of external and internal causes; and, as will be seen, the nervous power is susceptible of even more remarkable influences (§ 226–232, 725).

201, a. The last section leads me to consider the third kind of sensibility, or what I have denominated sympathetic sensibility (§ 197). Its office will explain the qualifying term sympathetic, which appears to be necessary to avoid the confusion which prevails in the application of the general term to the distinct offices of exciting acts of intellection and of influencing organic motions, and of producing involuntary motion in animal life. There was a radical objection to Bichat's designation of irritability as organic sensibility (§ 193); but in the present term there seems to be a peculiar advantage (§ 451, d).

"Impressions," says Müller, "conveyed by the sensitive nerves to the central organs are either reflected by them upon the origin of the motor nerves, without giving rise to true sensations, or are conducted

to the sensorium, the seat of consciousness."

When light produces vision, or odors give rise to agreeable sensations, it is due to specific sensibility. The mind perceives, and the effect goes no farther; there is no extension of the impressions beyond the sensitive nerves. Again, the light or mechanical irritants are productive of pain, and the effect is limited in the same manner. But here there is no specific sensation. It is the same in all the organs of sense. This, therefore, is due to common sensibility. At another time, however, the light induces a paroxysm of sneezing, or the odor syncope or disease. Here is a perfectly new train of results, the principal of which are in parts distant from the direct seat of the impressions. The primary influences have been propagated upon various organs by the nervous centres through the system of motor nerves. These influences, therefore, have called into action another modification of sensibility, and that is the sympathetic (§ 450, &c., 464, 514 k-m, 902).—Note D p. 1114.

201, b. This variety of the common property, like specific sensibility, belongs to certain parts only of the nervous system, and is the medium through which impressions upon all parts are transmitted to the cerebro-spinal axis, in the function of sympathy. Perception, and true sensation, therefore, which is rarely an attendant phenomenon, are not necessary to the office of this modification of sensibility, nor is a continuity of the nerves with the brain. Reflected motion may be as readily excited through the spinal cord as through the brain; "and we are in possession," says Müller, "of no facts which prove that the spinal cord, when separated from the brain and medulla oblongata, can be the seat of true sensation. The reflected motions excited by the irritation of the surface in decapitated frogs are no proof of this," The ganglia of the sympathetic nerve are, also, centres.

201, c. Sympathetic sensibility appertains to what are denominated the sensitive nerves, and the sensitive fibres of compound nerves, which are also, in part, the instruments of common sensibility. But, a remarkable anatomical distinction, and which goes far to sustain the variety of sensibility which is here indicated, is found in the sensitive fibres of the sympathetic and pneumogastric nerves; which possess, in the most exalted degree, the power of transmitting organic impressions to the nervous centres, but which are nearly destitute of common sensibility. Indeed, it is through this system of sensitive fibres that the whole organic department maintains the specific relations of its several parts (§ 129, 523, nos. 1, 2, 3, 6, 1037, b).

201, d. The impressions transmitted through sympathetic sensibility may be received either by the brain, spinal cord, or certain parts of the ganglionic system (§ 520); and either connectedly or independently of each other. When thus received by the nervous centres, they give rise to a development and transmission of the nervous power through what are called the motor nerves, and terminate in those influences which complete the function of sympathy, by giving rise to sensible or insensible motions, or modifying such as had existed.

202, a. The manner in which sympathies are brought about through the medium, in part, of sensibility, and the failure of impressions upon common and specific sensibility to generate sympathy, or to excite the influence of the motor nerves, and the absence of sensation in the former case, and the admissible absence of the brain, as well as other peculiarities, prove, abundantly, the existence of this third kind of sensibility. Besides, also, the prominent demonstrations to the foregoing effect which occur in disease, this modification of sensibility is in universal operation in healthy states of the body; as manifested in respiration, and in the concerted action with which the various organs carry on their respective functions. Through this modification all parts transmit to the cerebro-spinal axis special influences that are relative to their existing conditions, and these influences are propagated through motor nerves, and maintain a harmony of movements. These reflex nervous actions are, therefore, universal and perpetual.

The special function of this kind of sensibility, and its co-operation with the nervous power in the function of sympathy, will be farther considered along with that function, and the function of motion, and again under the laws of sympathy, and the modus operandi of reme-

dial agents (δ 1037, b).

202, b. It may be now said, however, that when sympathetic sensibility contributes to motion, whether in organic or animal life, or whether sensible or insensible, it is through impressions received and transmitted by this property to the cerebro-spinal axis, or to the centres of the sympathetic when a medium of reflex action, and a consequent development of the nervous power, which power then operates, through motor nerves, upon the organic irritability of parts which are brought into motion.

203. Like specific sensibility (§ 199), and the organic property, irritability (§ 190-192), sympathetic sensibility is variously modified in different parts, by which it is adapted to the reception of impressions from agents of particular virtues, and for their transmission to the nervous centres, and for the ultimate generation of true sympathy; while the same agents fail of these effects in other parts (§ 133, &c.)

204. Another manifest contradistinction between sympathetic, and common and specific sensibility, is seen in the general failure of impressions made on sympathetic sensibility to act upon the mind, and therefore in the ordinary absence of all sensation. If sensation be an attendant phenomenon, it then arises from impressions simultaneously made upon common sensibility (§ 445, 464-467, 473, no. 5, 474, no. 4, 523, 1037, b).

3. MOBILITY.

205, a. Mobility is the property by which all motions are carried on in animals and plants. It is peculiar to the solids, though some late physiologists have ascribed it to the globules of blood, while others have mistaken the globules for entozoa (§ 233, 253, &c.).

205, b. Sensible and insensible contractility, as employed by Bichat, and muscular power, are bad substitutes for the name mobility. They lead to erroneous conclusions; since the heart, blood-vessels, and other muscular organs dilate or elongate, as well as contract, through the same vital property; and motion occurs in various tissues.—(Med.

and Physiolog. Comm., vol. i., p. 150, 379-391.)

The terms sensible and insensible contractility limit the law of motion to simple contraction, while there must be often a corresponding active dilatation, or the part would always remain in a state of tonic spasm. Elasticity will never explain the dilatation of the heart, of the veins, &c.—(Med. and Physiolog. Comm., vol. ii., p. 147-156,

175, 176, 399-402, where this is fully examined).

206. The philosophical Macbride remarks that, "as irritability necessarily implies mobility of the animal fibres, this does not require to be considered a distinct property." If, then, the existence of mobility be thus implied, it is a distinct property; and when the phenomena of irritability and mobility are duly considered, it will be seen that they should be regarded in a separate sense. Irritability is certainly necessary to the exercise of mobility; but the former may be greatly exalted without a corresponding increase of motion. The distinctions are numerous and of great practical importance (§ 500, d).

207. The existence of mobility in plants is abundantly shown by the motion of their fluids, which no mechanical principle can interpret, by their secretions, and by other results analogous to those which depend, in part, on this property in animals. It is also manifested by the sensible movements of the leaves, blossoms, stamina, &c.; and from these we may reason analogically, and infer insensible motions of the sap-vessels, the secretory apparatus, &c., as is also done in animals (§ 1054).

Mobility, therefore, gives rise to sensible and insensible motions. They are generally sensible in animal life, and of either kind in organic (§ 476-492, 516, no. 2; also, Medical and Physiological Com-

mentaries, vol. ii., p. 150, 379-391).

208. Mobility is brought into operation through impressions made on irritability, whether by vital stimuli in organic life, or by the nervous power in either organic or animal life (§ 188). The philosophy of this will be considered along with the attributes of the nervous power, the function of sympathy, and the laws of sympathy.

209. If sensation apparently give rise to motion, it may be occasioned by the action of external or internal causes upon sensibility;

but this impression is imparted to irritability and then to mobility, before motion can follow (§ 195); or, from the intimate associations and analogies between irritability and sensibility, the two properties may be simultaneously affected by the same agents. Where, however, sensation is accompanied by motion as an apparent effect of impressions upon common sensibility, it probably arises in all cases from a simultaneous impression upon sympathetic sensibility (§ 198, 201, 202). This exact analysis is indispensable to our subject.

210. Irritability may be increased through an exalted state of sympathetic sensibility, and organic motions may be thus increased through sensibility; which is nearly the same as the foregoing law

(§ 209).

211. It is doubtful whether parts may be irritated without exciting mobility (§ 202); but it is otherwise with common and specific sensi-

bility, as in seeing, tasting, &c., and in pain.

212. Mobility, like irritability and sensibility, may be in a passive or dormant state, as in the ovum and seed, or as sensibility exists in the organic life of animals. All are roused by appropriate agents, and could not be roused were they not already present. Certain animals, such as the wheel, and the sloth animalcula, may have all apparent traces of life extinguished, may be completely exsiccated, and be speedily revived by heat and moisture.*

The first impression of semen, or of heat, &c., upon the ovum, or seed, is made on irritability, through which, as the next step in the process, mobility is roused into action. Then follow the new ele-

mentary combinations.

We thus learn, in part, that life is a cause, not an effect.—(Med.

and Physiolog. Comm., vol. i., p. 9, et seq.)

213. Sensible mobility is especially manifested in the compound organs, taken as a whole (§ 205). Insensible mobility occurs in the small vessels (§ 207). But, the palpable evidences of a special law of motion in the small vessels are apt to be sacrificed to the negative fact that the motion itself is not of a visible nature. As well might we deny the existence of microscopical animals.

214. The insensible motions in organic life are the most important that occur, especially such as take place in the extreme capillary vessels; since these are the instruments of all the most essential actions

and phenomena of life, and of disease.

215. Voluntary motion is brought into exercise by the will and nervous power, as will be set forth under my consideration of the latter property and the function of motion (§ 222-233\frac{3}{4}, 500 d). The essential difference, therefore, between the motions in animal and organic life lies in the nature of the stimuli; voluntary motion requiring the exercise of the will, while the organs of organic life rarely obey the stimulus of the nervous power when excited by the will (\(\phi\) 500 e). It is probable, also, that mobility has a peculiar modification in the muscular tissue of animal life.

Notwithstanding mobility, in animal life, is always subject to the nervous power, motion is here, as in organic life, independent of the nervous system, excepting as supplying a stimulus (§ 483, 486).

^{*} See Spallanzani's Experiments in Opusculi di Fisca Animale, Opere, t. vi, p. 482-556.

4. VITAL AFFINITY.

216. It has been seen that the elements of organic compounds are very differently combined from those of inorganic (§ 32, &c.). Hence has arisen the term vital affinity, as denoting a property peculiar to plants and animals, by which all their elements are united and maintained in combination. When death takes place, chemical affinities operate, and resolve the organic into inorganic compounds, or into their simple elements (§ 174).

217. Vital affinity exists in modified states in the two departments of organic nature; since, in plants, it unites the simple elements into organic compounds, while in animals, it can operate only upon compounds of this complexity. Vegetable organization is, therefore,

more of a creative nature than animal (§ 13).

5. VIVIFICATION.

218. By vivification, in conjunction with vital affinity, life is bestowed upon dead matter. The elements of matter are, essentially, combined into organic compounds by vital affinity; but there is a progressive vitalization of the organic compounds till they become united This shows that vital affinity must have an associate with the solids. power of vivification.

219. Vivification belongs, particularly, to the assimilating organs, though its energy must be great in the gastric juice. It has natural modifications in all parts, and presents distinctions between plants

and animals.

220, a. Vital affinity and vivification, like the other properties of life, are susceptible of morbid changes. This gives rise to changes in the general vital character, and in the composition, of the solids and fluids.

These changes in composition are inferred upon principle, as well as from observation (§ 666, b). No chemical analysis can detect them, unless it be an alkalescence or an acidity of the secreted fluids, or changes in the urine; and even these imperfect results are often surrounded by objections (§ $5\frac{1}{2}$ b, 53, 1029, 1030).

220, b. Changes in some of the secretions, as in the milk, may be brought about by temporary influences, and independently of disease, as by emotions of the mind, the action of cathartics, &c. These also affect the condition of organs and their products in the various states of disease; and upon this depends the art of medicine (§ 852, &c.).

220, c, The alterations which take place in the solids and fluids are always the same in any given condition of the affected properties of life. They are, therefore, constantly liable to variations during the progress of disease, and are various in different diseases, and according, also, to the nature of remedial influences, and of those other causes by which they are affected independently of disease (§ 672).

221. The changes which arise in the solids and fluids from morbid conditions never approximate the condition of dead matter (§ 674).

 $221\frac{1}{2}$. Changes in organic compounds may be the result of the direct action of physical agents, but are generally owing to alterative influences of direct or reflex nervous action leading to disease, and something to the natural law that the nerves impress a special condition upon animal compounds, both solid and fluid (§ 69, 226, 399, 405, 446 a, 455, 456 a, 461, 485, $488\frac{1}{2}$, 489, 512, 740, 952).

6. THE NERVOUS POWER-ITS DIRECT AND REFLEX ACTION.

222, a. The analysis which I shall make of sympathy establishes so clearly its functional character, that I shall remove it from among the properties peculiar to animals, where it has been hitherto placed. In defining this function, generally regarded as a property, I shall introduce the nervous power, upon which, in connection with sensibility, the function depends (§ 201). This is reflex nervous action.

222, b. The philosophy of the operation of the nervous power in producing motion, under all its various aspects, as manifested in its natural regulation of organic functions (§ 202), or by its other reflex actions as induced by morbific and remedial agents, or by the influences of disease, in the motions which are generated in the organs of organic life by the passions and analogous affections of the mind, in the movements of the voluntary muscles, in the production of sudden death from all causes, as well as the solution of other relative problems, and the physiological interpretation of the recognized laws of sympathy and their general introduction into pathology and thera-peutics, were originally attempted by myself in the Medical and Physiological Commentaries, and subsequently, and more extensively, in my Essay on the Modus Operandi of Remedial Agents.* Should the exposition there and now set forth prove to be well founded, it must necessarily result, sooner or later, in the overthrow of all the mechanical and chemical hypotheses in physiology, consign to its well-merited oblivion the humoral pathology, and place upon its true foundation the operation of remedial agents.—See Rights, &c., p. 912.

223. The nervous power appertains to the vital principle, resides exclusively in the nervous systems, and is, therefore, peculiar to animals (§ 184, b). It gives rise, however, to results in organic as well as animal life. These results, also, are far more numerous and important in the organic than the animal mechanism, while sensibility is especially designed for the latter. Unlike sensibility, also, in its function of sensation, perception is not necessary to the operations of the nervous power, nor does the latter, like sensibility in its office of producing sensation, require a continuity of the nerves with the brain for reflex or direct action, especially in organic life (§ 209, 507).

The nervous power is constantly, though, for the most part, in insensible operation throughout the organic mechanism, modifying the actions and animalizing the products of all parts. For this special reason I have endeavored to show that the nervous power is superadded to the vital principle of animals, and that the complexity of organs and functions which it is designed to subserve, and the absence of its phenomena in plants, afford a substantial proof that the property belongs to animals alone (§ 1041.)

224. The nervous power is exerted, especially, through what are denominated the motor nerves and the motor fibres of compound nerves, or "nerves of motion;" these nerves, however, being mainly dependent for the nervous power upon the brain and spinal cord (§ 201).

Nevertheless, there is reason to suppose that the nervous power is implanted in the motor nerves, as well as in the brain and spinal cord. The phenomena of contiguous sympathy, as when inflammation of the liver, the lungs, &c., is relieved by blisters, over the region of the

^{*} MED. AND PHYS. COMM., 1840.—Essay, &c., 1842.

affected organs, cannot be traced through the cerebro-spinal system. excepting in its connection with the ganglionic, which supplies, in such cases, the immediate centres of reflex nervous action (§ 893). There exists a great fundamental distinction between the cerebro-spinal and ganglionic systems, the former of which is allotted especially to animal life, the latter to organic (§ 113); and, although the cerebro-spinal be associated in function with the ganglionic, purely cerebro-spinal nerves exert no influences upon the organic functions, not even the pneumogastric till independent life begins, while the ganglionic supplies the stimulus to organic muscles, combines the organic viscera, and determines exciting and modifying effects upon all their actions, by which the secretions are variously increased or diminished, and the organic products imbued with the peculiarities that distinguish them from the organic compounds of plants; and what is of vast practical importance, it is owing to those physiological differences that morbific and remedial agents operate, essentially, through the sympathetic system (§ 113, 409 h, 422, $461-461\frac{1}{2}$, $475\frac{1}{2}$, 500 g, 524 a, no. 7, $891\frac{1}{2}$ g, k, $893\frac{1}{2}$).

225. Like irritability, sensibility, and the other properties of life, the nervous power is capable of being acted upon by external and internal causes, both mental and physical, of being increased, or diminished, or altered in kind, according to the nature of the causes (§ 200, 203, 258).

226. The nervous power possesses the remarkable characteristic of being a vital agent to the property irritability (§ 184 b). It is also liable to artificial modifications from the operation of physical and mental causes upon the nervous system; and its influences upon irritability will correspond with the nature of its modifications; being thus rendered a vital stimulus, or a vital depressant, or a vital alterative (§ 150). When, therefore, this power operates in any unusual manner, organic and animal motions, whether sensible or insensible, will be variously modified, or produced, by calling mobility into exercise, according to the nature of the influences exerted upon the power, and products will vary accordingly. This grows out of the natural office of the nervous system of exciting and modifying organic actions and their results (§ 461).

227. The nervous power is brought into unusual operation very variously, according to the seat and nature of the exciting cause (§ 951).

1st. Its operation is excited in a direct manner by irritants, &c., applied to the brain, to the spinal cord, and to the motor nerves. It is also excited directly by cerebral or spinal disease, by the passions, mental emotions, imagination, intense reflection, and by the will. This I call direct nervous action (§ 222 a). In all the cases, the nervous power will be rendered stimulant, or depressant, or alterative to the organic properties and functions, and variously energetic according to the nature of the operating cause, and the intensity and suddenness with which it may operate (§ 480, 743, 951). In blushing, the power is rendered stimulant; by fear, depressant; by grief, anger, hope, &c., alterative (§ 844). These effects are also commonly very sudden, especially the physiological. Even such as are morbific are often almost instantaneous; and this rapidity of change ceases to be remarkable when we regard their near coincidence with the natural results, and that the same principle is involved in voluntary motion.

A close analogy subsists between all the foregoing direct causes and all the physical agents of life, whether natural, morbific, or remedial, as the latter may develop the nervous power through sensitive nerves. These analogies will have been variously illustrated. They

evince the simplicity of fundamental principles and the relationship and perfect harmony which prevail among the whole, even those which are especially relative to mind and instinct as superadded to the simple condition of the vegetable kingdom (§ 323-325, 818½).

2d. The reflex action of the nervous power is excited through the medium of sympathetic sensibility (§ 201-203). This complex process results in the true function of sympathy. Impressions are made by physical and mental causes, by disease, &c., upon the foregoing variety of sensibility, which I call sympathetic from the office of the sensitive conductors in this function of reflex nervous action. The impressions are then communicated to the cerebro-spinal axis, or to other central parts of the nervous system, and there bring into operation. and variously modify, the nervous power (§ 224). The power, thus developed, thus influenced, or so modified in kind that it partakes of the nature of the transmitted impressions, which are more or less coincident with the virtues of the remote causes, is then exerted, through the motor system of nerves, upon the organic properties of distant parts, or of the nervous system itself (§ 208, 209, 462-469), by which those properties, and their resulting functions and products, are variously affected according to the foregoing circumstances. From this fact it also results, that the modified conditions which are brought about by the nervous power, when the preternatural operation of this power depends upon external causes, whether morbific or remedial, are more or less analogous to those changes in the organic conditions which are wrought in parts by the direct operation of the same causes (§ 188, 657 b, 503-505, $891\frac{1}{2}$ k 893 e, 902, 904 a, 951 c, $990\frac{1}{2}$).

228, a. It thence follows, that there is imparted to the nervous power, by the foregoing means (§ 227), more or less of the characteristic virtues of the remote causes, but under the influence of its own nature, by which the nervous power is substituted for those causes, and thus reaches, with its acquired attributes, and their various effects, every part of the organization, and, often, with great instantaneous-ness. It appears, therefore, that this constitution of the nervous power is wonderfully suited to the various exigencies of life; while, as will be seen in section 232, it grows out of its physiological nature as

a regulator of organic actions (δ 1057, 1075, 481 d).

228, b. It is also an important law that the nervous power is variously influenced in its morbific and remedial action by slight variations in the intensity of the operating causes, whethermental or physical; though a determination is simultaneously given to its action by the numerous other conditions already mentioned, and which may happen to be present. Thus, an impression from cold, as a blast of air, or a drop of cold water, upon the skin in syncope, will rouse the respiratory organs. Another impression from the same, and under other circumstances, will excite catarrh, or pneumonia, or articular rheumatism. One degree of impression upon the stomach by tartarized antimony will determine the nervous power upon the respiratory muscles (as will cantharides upon the bladder, or mercury upon the salivary glands), and vomiting is the consequence; while it simultaneously reflects the same power upon the skin, and other organs. and of which perspiration, &c., is a consequence. In smaller doses, the respiratory movements are not affected, but only the condition of the skin, &c., and in lesser degrees. But, these examples embrace only certain parts of the influences in each case; while in others they are far more complex, one sympathetic result becoming the cause of others, till, through a single impression upon the skin, various circles of morbific or remedial reflex nervous actions may be instituted.

229. When disease operates in the foregoing manner in exciting the nervous power, and determining it with alterative effects upon remote parts, or upon the nervous system itself, it often imparts to it a modification by which a similar condition of disease is generated in the parts upon which the power is thus determined. Hence the consecutive inflammations which are often springing up, sympathetically, in various parts. But, this depends, more or less, upon the nature of the organs secondarily affected, upon their precise condition as diverted more or less from their healthy states by other causes, upon temperament, age, sex, &c. When, therefore, the nervous power is developed by disease, other conditions varying more or less from the primary affection are observed among the common effects. For the same reasons, also, when morbific and remedial agents operate through the medium of the nervous power, the results may be very various.

230. If the nervous power be brought into preternatural operation in a direct manner (§ 227), as when impressions are made upon the brain, or spinal cord, or the trunks of nerves, or by cerebral disease, or when the mind or passions develop its operation, it is also liable to modifications, and corresponding effects, as when the impressions are communicated through the medium of the sensitive conductors. Thus alcohol, applied to the brain or spinal cord, increases the action of the heart and capillary blood-vessels, and so do anger, joy, hope, love, imagination. But, a watery infusion of opium or of tobacco, applied in like manner, depresses those actions, and so do fear, grief, and anxiety. We see, also, various other organic functions affected in a corresponding manner (§ 480-485, 489-492, 943, 945). In these cases, the nervous power is often determined, with more or less effect, directly upon the organic properties of the brain, and may extinguish them instantly. A sudden explosion of anger may, in this manner, induce apoplexy, while in other cases the destructive influence of the nervous power is expended mainly upon the heart. Inflammation of the brain determines the nervous power directly upon the cerebral vessels which carry on the morbid process, and thus increases its force and obstinacy. So with many morbific and remedial agents of a physical nature, which, when applied to the stomach, excite the nervous power indirectly, or through the medium of the sensitive fibres of the pneumogastric and sympathetic nerves, but in which cases the nervous power is reflected upon the organic properties of the brain. or of the spinal cord, or of the individual nerves, as well as upon those of other parts. Such is the case with all the narcotics, strychnine and analogous substances, prussic acid, aconite, &c., which bear specific relations to the nervous system; either exciting or removing morbid states of the brain or nerves (§ 487 g, 526 d).

231. It is not alone the general functions of tissues and of compound organs which are affected by the nervous power in the foregoing manner (§ 227-230), but equally, also, those of the intimate organization of all parts, upon which nutrition, vital decomposition, &c., depend. It always acts upon minute structure (§ 395, 1040).

232. The modifications of the nervous power now described (§

227-230) are analogous to those which we have seen to be exerted upon irritability and sensibility (§ 191, 200), and they spring from that physiological constitution of the nervous power which is designed for great natural purposes in the animal economy. This power is manifestly associated with the vital principle of animals (§ 184, b) as a regulator of their multifarious parts, by which the whole are maintained in harmonious action, or by which the varying changes and failures of some shall institute vital changes in other parts that shall contribute to the restoration of the former, or exempt the general organism from the evils which would otherwise arise (§ 455). tary motion (§ 215, 486), respiration, a permanent contraction of the sphincters, are also other final causes of the institution of the nervous power. The power is in perpetual operation in every part of the animal organization, though more obviously pronounced in some of its results than in others, as in the function of respiration, the permanent contraction of the sphincters, the motions of the iris, &c. It is, however, not less constantly operative, though with less intensity, in all organic processes, bestowing important conditions upon all products of an organic nature, solid or fluid, and forever stretches its universal sway, as a harmonizing power, over the whole organic mechanism. This power, therefore, is rendered exquisitely susceptible to the most astonishing variety of physical, vital, and mental causes; and, that it may feel and transmit the influences of the vital changes that may befall one part or another to other parts, for the maintenance of the great balance of functions, and to fulfill the office of restoration as well as of conservation, there is imparted to it, as to the other properties of life, a partial mutability in its nature, conformable to the various impressions exerted upon it, and by which it is rendered variously and usefully alterative to morbid conditions; and since, also, such alterative effects as are demanded by morbid states could not be exerted by a natural vital agent in its unmodified condition. Thus we have, in the obvious constitution of the nervous power, as manifest in its common functions, a principle of interpretation for all the variety of changes that are not less obviously exerted upon it by morbific and remedial agents than are plain its reflex and direct actions.

233. The nervous power does not generate motion either in animal or organic life (§ 476-492, 516, nos. 2, 7). It only influences the organic property mobility, upon which all motion depends, through the medium of irritability (§ 188, 205, 208, 209, 226). Even voluntary motion is entirely independent of the nervous system, excepting as the nervous power is a stimulus to irritability. In the production of this complex function several elements are concerned: 1st. The will, operating as a stimulus upon the brain, develops the nervous power; 2d. This power is then transmitted to the voluntary muscles, where it acts as a stimulus upon irritability (§ 226); 3d. Mobility is thus called into exercise, the immediate result of which is voluntary motion (§ 205, 206, 208, 209, 245, 256, 476 c, 486, 487, 492, no. 7, 500 d). However complex, and destitute of analogies in the world of mere physics, this phenomenon may be, I have no doubt that the solution which I have offered will be received by every philosophical mind which may attentively consider the nervous power in its connections with the motor nerves, and the experiments of Wilson Philip (§ 464,

&c., 476, &c., 1041).

Since, also, the nervous power has no existence in plants, their actions are alone influenced by the physical agents of life; and, having no sympathetic relation of parts, the diseases of one part are felt by other parts only through the common laws of nutrition, while, also,

remedial agents are curative by their local action alone.

2331. The nervous power, in a manner analogous to its determination upon the sphirecter of the bladder after the evacuation of the urine, may be propagated upon distant parts, with morbific or curative effects, long after the removal of the agent by which it was originally excited. This is owing to the continued change, or impression, wrought upon the part to which the agent was applied (§ 514 g, 516, no. 6).

2333. One of the most remarkable laws of the nervous power is that of its determination through particular nerves upon certain parts, according to the nature of the exciting cause, whether mental or physical, whether natural, morbific, or remedial, and equally so in animal and organic life; passing over, in the fulfillment of this law, various intermediate nerves of more direct anatomical connection. This is remarkably exemplified in many musical performances and feats of This special determination of the nervous power is most in conformity with the special influences that may bring it into operation, in healthy conditions of the body; but in diseased states, or where organs are but partially diverted from their natural state, a direction is more or less given to the determination of the power by these acquired susceptibilities (§ 500 j, k, 871). This peculiar attribute of the nervous power distinguishes it from the direct action of remedial and morbific agents, which, if taken into the circulation in efficient quantities, would often derange the universal body. But the same physiological constitution of the nervous power which renders it obedien; to the will in its transmissions to particular muscles, or to the passions in its effects on special organs in organic life, renders the power, when modified by remedial or morbific agents, and according to its precise modification and susceptibility of parts, equally determinate and circumscribed in its operation (§ 150-152, 838, 844). There is nothing in Nature more wonderful and paradoxical than this attribute of the nervous power; and while the facts which it supplies in connection with the operation of the will and the passions bear with the strongest analogical force upon the philosophy which respects the influences of morbific and remedial agents upon all parts distant from the seat of their application, that analogy is corroborated by the limitation of the morbific or remedial effects to certain parts of the organism.

 $233\frac{4}{5}$. It appears, therefore, that the nervous influence, reflex or direct, is generally the immediate remote cause of all changes beyond the seat of the direct action of other causes ($\S 644-647\frac{1}{2}$, 889 k).

GENERAL REMARKS UPON THE PHILOSOPHY OF LIFE.

234, a. Notwithstanding all the laws of sympathy, that are necessary to the full interpretation of the remote effects of morbific and remedial agents, are as well established as any laws in physics, they have not been applied to these important objects; but, on the contrary, those philosophers who have contributed most to their critical exposition overlook their pathological and therapeutical bearings, and cling to the doctrines of humoralism, and of the operation of remedial agents by absorption; nor have they applied, in the least, the nervous power in a philosophical manner to an exploration of the natural phenomena of sympathy. The oscillations of Newton, the contractions of Darwin, the vibrations of Hartley, the secretions of Galen, the galvanism of Galvani, the destructive forces of the chemist, and the caloric and the magnetism of wilder imaginations, continue to be adopted, and show as well by their great incongruity as by their failure, that the hypotheses are founded on imaginary data, and that each has neglected the phenomena of life (§ 189 b, 785, 1085).

234, b. I say nothing of those who still refuse their assent to the well-ascertained laws of sympathy, as manifested in the natural states of the body. These they have yet to study and to learn; but it may be well objected that their ignorance shall prove an obstacle to the

progress of knowledge ($\S 905\frac{3}{4}$).

He, indeed, must have been a very imperfect spectator of human events, who anticipates the acquiescence of ignorance or prejudice, or the ready concurrence of inferior minds, in the intricate problems which relate to the laws of the vital functions. The demonstrations of Philip have become obsolete in all but their abstract nature; and the discoveries of Prochasca, Sir Charles Bell, Müller, Hall, Valentin, and others, in the functions of the nerves, are either unknown, or unappreciated, by all but the erudite student or such as aim at erudition; and the very anatomical medium of reflex actions, through which the operations of the nervous power and the phenomena of sympathy appeal, as it were, to the senses as well as to the understanding, is apt to be regarded as an accidental or as a superfluous appendage of the body, or thrown in to embarrass inquiry by multiplying the complex ities of organic beings (§ 1039).—Rights of Authors, p. 912.

Coming to the different kinds of irritability and sensibility, or as these are modified by morbific and remedial agents, or by other physical causes, as well as the analogous modifications of the nervous power, and its remarkable attributes as a vital agent, its direct action as such when developed by causes acting directly upon the nervous system, or when brought into operation indirectly through the medium of sympathetic sensibility (§ 227), and other analogous facts which are equally substantiated by an endless variety of phenomena, they are pronounced by a no small number of the profession, even by writers who appear in the character of expounders of medical philosophy, as metaphysical speculations, or as imaginary hypotheses. Even life itself is regarded as a subtlety of the schools, or as a phantom of less reputable claims. "For my part," says Magendie, "I declare boldly that I look upon these ideas about vitality, and the rest of it, as nothing more than a cloak for ignorance and laziness" (§ 1034).

234, c. If, then, you object to the existence of a principle of life, why not to the existence of mind, to the imponderables, or to tangible matter itself (§ 168, 169, 175 bb)? Do you deny its several well-attested properties? Then why not deny the properties of the mind? Have you not, for the aid of the senses, a tangible analogy in the solar beam (§ $188\frac{1}{2}$ d, 234 e)? Do you cast aside all the phenomena of irritability and sensibility, and maintain that the action of internal and external causes, the mind and its passions, is exerted upon the structure alone, because you cannot see the properties (§ 169, 189)? Can

^{*} See Medical and Physiological Commentaries, vol. i., p. 397, 511, 512, 514, 515, as to Magendie.

you see the Maker of the eye, or did the eye make itself (§ 74)? Do the muscles move without a moving power? Are you not amazed at what you cannot deny, that the mutual co-operation of the mind and the brain, which results in willing, is limited in its action upon the body to exactly those parts where its operation can be alone useful to the animal, namely, the voluntary muscles; nay, more, that the will elects of these muscles such only as are precisely necessary to its present purpose, and bestows every imaginable degree of force within the limit of its power, and variously, also, on the several muscles which it may throw into simultaneous action (§ $233\frac{3}{4}$, 349 e, 500 i)? Is there nothing as improbable in all this as in the propositions of the vitalist? Consider how, on the other hand, those other acts of the mind, called the passions, so near akin to the will, judgment, reflection, are clearly ordained to operate in organic life for the moral and physical good of the being; or, if they be also the causes of pain and disease, the analogy of Nature shines out even here in placing them on a par with the morbific agents of the external world. If this be so, or a single fact conceded, how will you disregard the multitudinous phenomena of irritability and sensibility, or their various natural and artificial modifications (§ 64, f)? Will you consider an argumentum ad hominem? Do you, then, deny that you possess judgment, reflection, and the ability to discover truth? If you object not to this, you must concede the philosophy of these Institutes as to the foregoing properties of life, and by the same demonstration upon which that philosophy rests you must admit the imputed attributes of the nervous power, which are far more clearly and variously attested than judgment, reflection, or the ability to discover truth. Look at the experiments by Wilson Philip, Hall, Müller, Bell (§ 464, &c., 476, &c.). Look at the nervous system, and there you shall absolutely see. Or, do you require other aid for your senses, look, again, at the analogies which are supplied by the solar beam, by electricity, by galvanism, by magnetism. Consider how they astonish you in their overpowering influences upon all things but the living being. And yet you can not see how these destructive effects are exerted. You give up your senses when the needle traverses the compass, and stand in mute astonishment, gazing at the north for some sign that shall help the understanding as to the nature of the mysterious agent. But you see and feel nothing. Nor is this all; for the dismay of sense becomes inexpressible, when imagination surveys the interval of thousands of miles, through which the unseen force exerts its mystic sway. And so of gravitation. But the effects are strongly pronounced upon the sense of vision, and their frequent repetition begets an acknowledgment that there is something besides the tangible and visible qualities of matter which, operating through vast distances, maintains the needle in one everlasting direction, and the heavenly orbs in their undeviating rounds. And here, in the perpetual operation of magnetism, there is something to aid your conception of an equally unintermitting exercise of the nervous power (§ 1034).

234, d. Do you object to what I have propounded as to the artificial and temporary modifications of the nervous power (§ 227-232)? Can you state an objection, farther than that which has been just considered? Do not the infinite phenomena of sympathy mutually conspire together, without a contradictory fact, in proving the occurrence

of such modifications; and is there a single effect of morbific and remedial agents, operating through the nervous systems, which cannot be clearly, perfectly, explained by the doctrines which I have propounded in relation to the nervous power? Can a like affirmation be made of any other thing? But, you cannot see the modifications of the nervous power. Neither can you see the modifications of the electric fluid, as manifested under the conditions of electricity and galvanism; but, the effects of the latter make a strong impression upon sense, which grows into the belief that physical causes do, in reality, alter the conditions of electricity and turn it to galvanism, and those effects have actually engendered the expression of "modification of electricity." Here, then, is something for the senses, to aid them in their survey of the less tangible, but not less precise, and infinitely diversified, phenomena, that mark the artificial modifications of irritability, sensibility, and the nervous power. And, should you require a like assistance as to the natural modifications of irritability and sensibility, or even the existence of the different properties which appertain to the vital principle, you have only to regard the solar beam, and the solar prism, and try experiments with each prismatic color $(\S 188\frac{1}{2}, d).$

234, e. Do you marvel at the rapidity with which the nervous power moves in its operations? Consider, then, the incomprehensible velocity of light,—200,000 miles in a second of time; or the more rapid apparent motion of the electric fluid. Or, take the more probable doctrine of the undulations of light, and this will be yet more conformable to what is probably true of the nervous power. Of the undulations, then, we have not less than 458,000,000,000,000,000, for the red ray; 535,000,000,000,000,000, for the yellow ray; 727,000,000,000,000,000,

for the violet ray, in a second of time.

I say, when we think of the physical effects of electricity, galvanism, magnetism, and of light, and more especially when we attempt to think of the inconceivable rapidity with which the undulations of light are propagated, we shall have no difficulty with what I have attributed to the nervous power in resolving the phenomena of sympathy, voluntary motion, &c., and when, also, we reflect that those very undulations, according to their variety, produce on the retina all the impressions that are requisite for every phenomenon of vision, and that every impression, which is thus produced, must be transmitted to the brain, before the sense of vision can be excited (§ 188½ d, 500 k).

If, also, the retina be thus sensitive to the undulations of a substance which is so imponderable that it is doubted by many whether the substratum of light be actually material, we shall have no difficulty, I say, by the aid of this plain analogy, in making the same philosophical use of the vastly more numerous and unique facts that are supplied by animal life, or in apprehending that the virtues of more substantial agents, whether morbific or remedial, may, in like manner, exert powerful impressions upon the properties of every part, both nervous and organic, and that such influences may, equally with the impressions of light, be transmitted to the brain and spinal cord, and establish impressions upon the parts in conformity with the virtues of each agent (§ 503).

The undulations of light are excited by the various objects from which they proceed. And so of the nervous power. It is not in tran-

situ, a movable substance, but, like the principle of light, is every where diffused through its appropriate medium, and, like that principle, is brought into operation by exciting causes. Is it difficult, however, to imagine how the nervous power can move with the velocity of light in parts so dense as the nerves? It is less difficult than the comprehension of the admitted fact that light traverses the diamond as rapidly as it does ethereal space (§ 175 b, 188 d). Do you still marvel as to how the nervous power should induce or subvert diseases? Were you not equally in the dark as to the modus operandi of the solar beam in its various agencies upon inorganic compounds, till a few obscure phenomena led to the hypothesis of undulations? But, what have you gained by the undulations? Can you tell us how these inconceivably small motions operate, without a resort to absolute assumptions? Are you any more convinced than before, that the phenomena of light are realities, or have you been aided a whit, by these discoveries, as to your former knowledge of the laws of light? You tell us that not only the well-known colors of the solar spectrum possess, individually, specific properties, but that "each of these comprises rays differing in constitution, and differing in refrangibility, and that, doubtless, to each one specific effects are due."* You show the physiologist a few positive results, and he believes the analysis, and the existence of the several rays; though he may greatly discredit your philosophy of the effects as manifested in a department of nature which you study only under influences supplied by the laboratory (\S 188 $\frac{1}{2}$, d). But, you tell him, also, that the solar ray embraces "other principles which are invisible," and you call upon him to admit the existence of these, notwithstanding he cannot see them (§ 175, bb). The physiologist, however, readily admits their existence upon the strength of the few facts which imply the operation of an invisible agent; and he does so because he is a physiologist. But, taking your own rule of judgment as to a vital principle and its several properties, you were doubtful whether he might demand more tangible proof; and, accordingly, you prepare him for an admission of your premises by a mode of reasoning which you reject, contemptuously, when the physiologist sets forth his endless series of facts which prove, each one, the existence of properties peculiar to living beings. You prejudge the case, as it were, by impugning his understanding, unless the induction be conceded. You tell him, that, "just in the same way that I am willing to admit the existence of forty simple metals, so, upon similar evidence, I am free to admit the existence of fifty different imponderable agents, if need be" (§ 175 bb). The physiologist requires you to admit but one, and, with this one he explains, with perfect consistency, all the processes of living beings, all the phenomena in physiology, in pathology, and therapeutics, while no one of them can be interpreted without the agency of such a principle.

234, f. But again, I say, what have we gained in a practical sense, or as to the modus operandi, or the laws of light and heat, or of the constituents of the solar ray, by the discovery of the undulations, or by any supposed decision of the question as to distinct rays or modifications of a common ray, or even by the prismatic colors? Nothing whatever; no more than has been gained, in a useful sense, by microscopic explorations in physiology, but with the greater advantage

^{*} Draper's Treatise on The Forces which produce the Organization of Plants, p. 103.

of more precision, and more accomplishment to science, and without the pernicious hypotheses of the latter. And can the same affirmation be made of our knowledge of the properties of the vital principles, and of their natural modifications in different parts, and those which are induced by morbific and remedial agents? On the contrary, we see this knowledge every where converted to the most important uses of organic beings, not only in a direct practical sense, but in unfolding the great laws by which they are governed. This knowledge, indeed, is the great foundation of physiology and of the healing art.

Do you object to the relation which sympathetic sensibility bears to the nervous power (§ 201), and the relation of the nervous power to irritability (§ 226), in the phenomena of motion? Have you any better data for your conceptions of the relation of the magnetic pole to the needle; and to explain that relation, do you not admit a peculiar imponderable, invisible agent, which acts upon the properties of the needle? Do you understand any better, or have you any better facts respecting, the relation of physical agents to the mind, in the phenomena of sensation? You obtain your ideas of matter through the operation of physical agents upon the intellectual part; and how will you explain the access of those physical means to the spiritual substance unless you also admit the physiological property, sensibility? What intelligible connection is there between the properties of mind and the motions of the brain? What intelligible connection between the stimulus of the blood and the motions of the heart, or those motions which attend the generation of bile and all other organic products, unless you admit a principle of life? The forces of life are concerned about sensation in a peculiar manner, and there would be a violent interruption of the law of analogy were there not something intermediate between mind and matter, a bond of union, as it were, through which impressions upon the senses should reach the spiritual existence. We may fancy it to be electricity, or the chemical forces; but, this no more aids our comprehension, through the known phenomena supplied by these causes, as to the communications from matter to the immaterial, thinking existence, than if we regard the nerves, per se, as the only medium. We therefore turn our reason to the special phenomena, and find a property in universal operation throughout the body, as the medium through which certain kinds of impressions from physical agents are transmitted to the mind. But, we find, also, another analogous series of phenomena which force us to the conclusion that these depend, also, upon a certain modification of the same property as that through which impressions are made upon the mind by external objects. We see, also, that these transmitted impressions give rise to another endless series of peculiar results, which have their point of departure in the nervous centres; and we see, too, that each one corresponds with, and confirms the others, in the several series respectively. We learn, besides, that those of the last series are analogous to the direct effects of vital agents, healthy, morbific, and remedial, upon the organs which are the immediate seat of their operation. Hence, we conclude, inevitably, that there exists what is denominated the nervous power, with all the capabilities which I have ascribed to it, and that it is brought into operation through the same channel of sympathy as the mind when sensible objects exert their effects. The mind, and the nervous power, are, therefore, so far on a par. Each is an agent, each gives rise to sensible and insensible motions, and modifies variously the ordinary results when themselves are affected in an unusual manner, and each is brought into operation by analogous causes. The mind, through the properties of life, forms a special bond of union between itself and certain parts of the organization; the nervous power, another special bond between the same properties of the vital principle and other parts of the organization, and by which, and by the perpetual operation of that power, the whole organic mechanism of animals moves on in a well-balanced, concerted action. Thus are the properties of the mind, the properties of the vital principle, and the sensible mechanism, all mutually related to each other, and bound together by laws as precise as those

more simple ones which rule in the inorganic world.

234, g. We need not, therefore, inquire into the intrinsic nature of the nervous power, or of the organic properties. It would be as absurd as to interrogate the nature of gravitation, or of any other property of mere matter, or even matter itself; though we may well say what the nervous and organic powers are not, and thus save much speculation and its resulting practice. It is enough that we know their existence and the laws they obey. This is all that can be philosophically or practically useful. With these we are about as well acquainted as we are with the laws of gravitation, or of light. An ignorance of the nature of the principles or causes affects in no respect our study of their laws, of their modes of operating, or of the influences to which they may be liable. Their laws, like the laws of galvanism, or of optics, must remain the same, whatever theory may be adopted as to the nature of the causes.

Inquiries, therefore, so obviously beyond our reach as the absolute nature of the vital principle, or any of its properties, should never raise our curiosity, much less receive our attention. Their pursuit vitiates the judgment, diverts the mind from practical and useful in-

quiries, and renders it prone to speculation.

But again, I say, we know enough of the whole of this subject for the purposes of philosophy, and for the good of mankind, by the phenomena alone; and since the phenomena of organic beings are far more diversified than those which relate to inorganic matter, so also should we be as contented with the former as with the latter, and apply them in the same philosophical and practical manner. We also know enough of physics to marvel at nothing in organic beings which may be utterly different from the constitution, the phenomena, and the laws of inorganic matter; and, if it seem mysterious that such an agent as the nervous power should exist, with the characteristics which I have assigned, it will become less wonderful when we reflect upon the phenomena of the immaterial mind in its connection with organization, as in muscular motion, blushing, palpitation, syncope, apoplexy, &c., or even upon the velocity of light, the inconceivable rapidity of its undulations, its laws, its effects, &c.

All that we can know of the nature of any substance, material or immaterial, is by the phenomena it manifests. Where these are the same, or closely allied, as in electricity and galvanism, we may be sure that the essential causes are the same. But, where great and striking differences exist, and more especially where there are no analogies in the phenomena, as between the nervous power, or the

organic properties, and all inorganic agents, substances, or causes, we may be equally certain that the agents, substances, causes, or powers, are as different from each other, in their essence, as in their phenomena (§ 1085).

It follows, therefore, that the nervous power, and the organic properties, are, respectively, sui generis; having no analogies in the inor-

ganic world.

The phenomena which different agents, powers, or causes, manifest, are so unlike each other, that different modes of investigation must be pursued to arrive at a knowledge of each; and the phenomena will be just as conclusive of the nature of one substance or power as of another. A stone, for instance, affects the sight, and touch; it appears of a certain size, shape, color, &c., or it is hard or soft; if analyzed, it is found to be composed of several distinct substances, each of which manifest other phenomena; and this is all we know of the nature of a stone. And so of magnetism, galvanism, light, heat, and whatever else appertains to the inorganic world. We examine their manifestations, and compare them together, and distinguish different things from each other by the manifestations or phenomena of each. But, there are groups of phenomena which have certain general resemblances, and these we arrange into genera or families, as the several earths, metals, gases, &c.; but the specific distinctions always remain, so that by the phenomena peculiar to each species we can always distinguish one from another. Just so it is in respect to the physical and chemical powers. The means of knowledge are of the same nature in all the cases, and the proof is as good in one case as in another.

Coming to plants and animals, a general survey of their phenomena shows us that they have no other analogies, of any importance, with the inorganic world, than in the elements of which they are composed. These are derived from the inorganic kingdom; and here the similitude ends. If we investigate the phenomena analytically, they come upon us in a profusion wholly surpassing those of inorganic beings, and without the most remote resemblance. Here, therefore, we apply the same rule as to inorganic beings, and we learn by the same process of observation as much of the nature and powers of one class of beings as of the other, and the proof is as good in one case as in the other, though more conclusive in respect to organic beings, inasmuch as their phenomena are more various. By the same rule, also, we attain all the knowledge we possess of the soul, and, beyond that of Revelation, all that is relative to a Supreme Being; and we distinguish each from all the others, or bring them into relationship, in the same way.—See Correlation of Forces, § 1085.

The same mode of reasoning is, of course, applicable to what I have said of the modifications of the nervous power (§ 227-229), and

of the organic properties (§ 133-156, 188-215).

234, h. We are, however, so much the creatures of sense, that the majority will probably still go on explaining every thing appertaining to life by some tangible or visible cause, or by some laws with which we fancy ourselves to be better acquainted. I have already cited several examples; and if we take up any writer, indifferently, it is more than an equal chance that the authorities will be increased. Thus, here is Sir Gilbert Blane's excellent work on "Medical Logic."

"The changes," he says, "accomplished by the actions of life may be conceived to be effected through the agency of some imponderable fluid; such as electricity, light, or magnetism. We may conceive, for instance, that each gland may be furnished with a sort of voltaic apparatus for effecting its specific change." The same doctrine has been adopted by a host of medical philosophers of our own times. But, did any of the foregoing agents ever produce, out of the organic being, a single one of the phenomena of life? Did they ever give rise to one of those phenomena in a dead subject, although the organized structure remain unimpaired; as in cases of instant death from hydrocyanic acid, nux vomica, or from a needle thrust into the medulla oblongata? Is not the whole hypothesis contradicted by all that is known of the effects of those agents? It is the merest assumption to sustain an unintelligible and absurd hypothesis to affirm that structural derangement is necessary to death. If galvanism, the chemical forces, &c., be the immediate cause of the deposition which constitutes the interstitial growth, what bestows vitality (or life, if it be preferred) on the new-formed matter? Or, if this vitality be imparted by specific powers of the formative instruments, why should not those powers be adequate to the entire work (§ 64)? Why so great a violation of the most common rule in philosophy as to introduce other forces, whose great office is to pull down, and whose results are confusion?

234, i. The whole art of medicine consists in producing certain impressions upon properties or powers that are wholly unlike those which rule in the inorganic world. It will not answer to talk of modifying the operation of galvanism, magnetism, gravitation, light, chemical affinity, &c., by an emetic or cathartic. It must, however, come to this, if you will have it that those forces preside over organized beings, or even if they be allowed to have a subordinate agency (§ 175, d, 360, 409 k, 446 a, 488 $\frac{1}{2}$, 493 cc, 500 nn, 893 a, 893 $\frac{1}{2}$).

235. Finally, the phenomena of life are as easily comprehended as those of inorganic matter, and denote as clearly, and even more so, the nature of the causes. Who will demonstrate the nature of those physical properties by which foreign agents produce their impression on the properties of life? And yet so accurate is our discrimination among them, as prompted by the vital signs which they produce, that it is one of the most important objects of the physician to select from the multitude of cathartics, emetics, &c., a certain species whose properties shall correspond with the modified signs of the properties of life; and, it is no unusual phenomenon, that, of the whole range before him, he decides with accuracy that there is only one medicine which is well suited to the case. And his conceptions of the specific properties of the agent, and of those of the organization, even in the modified state of the latter, are so comprehensive that he may foretell their united result. He knows as much of the properties of life as of the remedial agent. He knows them far better; and that he admits their existence and specific nature is manifest from his deliberate action. Whoever prescribes for disease upon any other ground is a mere charlatan.

Who, again, will define the nature of cohesion, gravitation, chemical affinities, &c.? Like the properties of life and of spirit, and their relations to matter, their existence is only inferred from certain uniform phenomena, and from such, alone, we deduce their relations to

objects of more sensible demonstration; and this is all we know of the sensible objects themselves. We reach the connection between common matter and its properties, between the vital properties and organized structure, between the intellectual and moral faculties and the nervous system, the concurrence between them in the production of certain effects, and the differences in the nature of the several properties, by a common process of observation. There are mysteries attending the same conditions of the whole which must be left to the sole comprehension of the Author Who intended the whole to subserve the purposes in which we are alone interested; Who has wisely secured to Himself the nature and control of primary causes; and Who has thereby restricted our inquiries to the only useful end of knowledge, the existence of the causes, and their various phenomena and laws. These may be so employed as to answer the wants, the conveniences, and the various exigencies of intelligent beings. Those are the springs of action which it might be unsafe for man to understand.

236. From what I have hitherto said on the subject of life it must evidently be regarded, in a philosophical sense, as a cause, not as an effect. The functions and other phenomena are the effects. This construction, which I have also set forth in my Essay on the "Vital Powers" in other demonstrative aspects, is indispensable to any sound principles in medicine. All effects have their causes; and this simple principle obliges us to look for a cause of the phenomena of life. It is with the conditions of that cause, ascertained through the medium of its effects, that all physiology and medicine are concerned.

237. The powers by which living beings are governed, cateris paribus, are always as precise in their operation, and bring about results as precise, as gravitation itself. But the properties of life are constantly liable to variations, and, therefore, there will be corresponding variations in their phenomena. Gravitation, and other physical forces, on the other hand, are immutable, and there are, therefore, no variations in the results of their operation. But it is also equally true that any given condition of the properties of life, connected with any given influences, is equivalent to the unvarying state of the physical forces. That particular condition, in conjunction with the supposed influences, always determines the same results, whether in health or disease. Every power in nature, when operating under given circumstances, always terminates in uniform effects. The uncertainties. therefore, to which the science of medicine is liable, or any other which has nature for its foundation, are owing to our inability to understand all the facts. If any remedial agent produce an effect at one time which it does not at another it is because the properties of life have been differently affected in the different cases; and there may have been, also, a concurrence of many other different influences. Nevertheless, in each case, the medicine operates according to established laws, and the modifications depend upon the difference of circumstan-Each combination of circumstances, however, always gives a uniform determination to the laws which govern the effects. Where the conditions are the same, the remedy in a certain dose will always produce the same results.

Although gravitation is immutable in its nature, we yet see something analogous to the foregoing influences upon the properties of

life in the manner in which the revolution of the heavenly bodies may be affected by their interference, in relation to each other, with the power as exercised by the sun; as seen in the erratic movement of comets. In either case the incidental influences may be calculated. and the results foretold,-conforming, in one case, to the laws of gravitation, and in the other to those of the vital force. The sameness of the physiological conditions enables us to calculate not only what will happen to-day, but through all future time. But, the vital conditions are subject to precise modifications at the several great eras or stages of life; but, being marked by uniformity, the results are forever the same, at each era respectively. The fundamental changes enable us, also, to foresee how the modified properties of life will be differently affected by vital stimuli, the new sympathies that will spring up, the different relations of sensibility to the faculties of the mind, the difference in the acquisition of knowledge, &c., at the several eras. From these natural and uniform modifications of the vital states, we may turn to those of a fluctuating and accidental nature, which grow out of the influence of climate, habits, employments, &c., and which may be not only as lasting as the individual, but may be transmitted to his posterity. As at the different eras of life, we here find, also, variable influences from the natural, the morbific, and the remedial agents, variable sympathies, &c., among organs, according to the artificially-modified condition of the properties of life. These conditions, however, are rarely exactly the same in any two individuals; but, they are strictly analogous in principle to the natural ones which distinguish the several stages of life, and, so far as they may be known in any given case, we may calculate, with great approximation to the truth, what will be the special characteristic phenomena that will mark the organic, the animal, and the intellectual existence of that individual (§ 153-156, 535, &c., 574, &c.).

Thus we have a series of analogies, in respect to the mutability of the properties of life, and corresponding results, which bring us upon the confines of disease; which consists, also, in certain modifications of the vital properties, but more profound, more various, and more transient (§ 176-182). Here lie the difficulties of medicine; difficulties attending our knowledge of the modifying causes, the influences they produce, the complications of sympathy, and other contingent circumstances. All these conditions must be known in any given case, to foresee, with certainty, any immediate or more remote result either of disease or of the action of any medicine, or of any natural vital agent. But, the properties of life being never very greatly varied from their natural character, we may come, by a careful observation of their varying phenomena, to a knowledge of their conditions, and to foresee the results, or such as may spring from the operation of medicine, from the different kinds of food, &c., with sufficient accuracy for all useful purposes. With this knowledge, we get at the most important laws of disease, general and specific, and build up principles which are more valuable in practice than ages of disconnected

experience (§ 149, 150).

238. I have said, that although instability is a prominent characteristic of the properties of life, and lies at the foundation of disease and therapeutics, these properties never undergo any radical change till they shall have lost their recuperative tendency. They are the only

attributes of organic beings that do not undergo absolute change and renewal. These properties must be forever present, without essential change of their nature, to carry on the work of decay and renewal, which are in perpetual progress in all the solids and fluids over which

the properties preside.

Hence an important law, that all hereditary predispositions to disease, and all impressions from morbific agents, which do not produce their manifest effects till the blood shall have undergone a renewal (as in hydrophobia, fevers, &c.), must be primarily exerted upon the properties of life, and that all the subsequent changes in the fluids and solids must be due to that original modification of the vital properties. To perpetuate the primary influences something of a permanent nature must receive the impression. Analogy, alone, would assure us that this receive the also equally true of the effects of all morbific relaxations.

bific and remedial agents (§ 666).

239. There is nothing more important to be known and appreciated than the endowment of the properties of life with a tendency to return from diseased to their natural states. This is the vis medicatrix natura, and is the immediate foundation of therapeutics. This, and this alone, has given rise to the art of medicine; since, by no artificial means can the diseased properties and functions of life be converted into their healthy state. It is also remarkable that the most efficient remedial agents institute their favorable effects by establishing new pathological conditions; which farther shows that it is nature alone which cures, and through the foregoing principle. That principle consists in the controlling influence of physiological laws, and,

without it, organic nature would become extinct (\dagger 853).

240. Connected with the foregoing law is another not less fundamental, and which shows the fallacy of reasoning from the effects of remedial agents upon healthy to morbid conditions. It is, that the susceptibility of all parts to the action of remedies, physical or mental, is very different in disease from what it is in health, and the nature and the results of the influences are greatly different in the two conditions. Take many of the most powerful agents, arsenic, tartarized antimony, iodine, &c., and when administered in certain small and repeated alterative doses they bring about the cure of the most obstinate and formidable conditions of disease; while the same doses may not manifest any action upon the system, or on any part of it, under circumstances of health. This manifestly depends upon an increased susceptibility of the organic properties, in their diseased conditions, to the action of foreign agents, and upon an increased disposition to undergo changes. And here we have opened a grand display of infinite Design, Wisdom, and Goodness, to mitigate the penalties of disease, and to preserve the human race. This law, which unfolds a principle latent in health, and by which morbid organic properties acquire susceptibilities to salutary influences from agents which in health would either produce no effects, or lead to untoward results, and its ally, the great recuperative principle (§ 239), impose the highest obligation on physicians to become medical philosophers.

7. THE MIND AND ITS PROPERTIES.

241, a. Reason and instinct belong to man; instinct alone to animals. Mind is commonly regarded as synonymous with reason, and

instinct a principle by itself. The latter is undoubtedly true of animals; but I would consider instinct, in relation to man, as a property of the soul; while in animals it is shorn of the great distinguishing attribute of man, the rational, immortal faculty. Independently of the specific facts which go to this conclusion, it has the strong ground of analogy in the more complex condition of the principle of life as it

exists in animals than in plants (§ 184, 185).

241, b. To simplify the discussion of this intricate subject, the word mind, with the foregoing explanation, and mental properties, so far as perception, the will, and the understanding, are concerned, may be applied indiscriminately to man and animals. Judgment and reflection are the great characteristics of reason; but, contrary to the usual representation, the understanding belongs as well to the instinct of animals as to the human mind. Many, again, may be disposed to consider the understanding a function, rather than a property; but this construction would suppose the operation of judgment and reflection, which do not belong to animals. The term is also employed in

other acceptations than the present.

241, c. The abstract manner in which metaphysicians have considered all the operations of the mind, while no one of them is performed without the co-operation of the brain, or a principal nervous centre, and originally elicited through the corporeal senses, proves to us that physiologists are best qualified to analyze the phenomena of the soul and of instinct, and to indicate their relations to the body, and the laws which they observe. There is also a mysterious affinity between the soul of man and the instinct of animals, of which metaphysicians take but little or no cognizance. This alliance is shown by the corresponding manifestations of perception, of understanding, and of the will in animals; by the amazing precision with which their habits are regulated; by the evidence of common passions; by the coincidence in the external senses of man and animals, through which they alike acquire a knowledge of external things; by the parallel in the anatomical structure of the brain of man and of animals which stand high in the scale; and by other analogies, which denote an affinity between the soul and instinct So great and various, indeed, are the evidences of the foregoing nature, that the special attributes of instinct are associated with the human mind; thus forming a connecting link, through the moral faculties, between rational and irrational beings.

Nevertheless, the phenomena of the human mind are infinitely superior to those of instinct, while the operations of instinct in animals greatly surpass any of its manifestations in man. Many special peculiarities concur, also, in demonstrating an absolute distinction between the rational mind and instinct. The latter, for instance, always moves, in each individual species of animal, in a particular, unvarying path, but differently in each species of animal.* It never diverges to improve its original endowments, or to add a gain which it did not possess in its infant condition. It is then nearly as perfect in its operations as at mature age; nor does one generation of animals gain upon its predecessors. How different with reason, and with the instinct of man! He passes through early infancy without a trace of the former, and with only that helpless development of the latter which ena-

^{*} Here I may say that analogy proves that there is but one species of mankind, since the manifestations of reason and instinct are the same in all.

bles him, with the foreign aid of reason, to imbibe the sustenance required by organic life. Unlike the instinct of animals, however, the corresponding manifestations become greatly multiplied as age advances; but it remains always far more circumscribed and imperfect, and often plunging itself, and leading reason, into violations of their natural functions. And what a contrast between the limitations of instinct and the progress and grasp of the human mind; the latter forever ranging through all the labyrinths of nature, investigating their phenomena, developing their powers, their subsidiary causes, and their laws, turning in upon itself and multiplying its knowledge, and enlarging its powers by its own independent efforts, laying up the gains of the past as a fruitful source of present good and of farther acquisitions, distinguishing good from evil, from which results the sense of moral responsibility, investigating its own attributes, and attempting even its own nature, and tracing up its existence to a Higher Power, as the Author of the Universe which was made for the contemplation and the enjoyment of mind (§ 175 c).

241, d. It is not an object, however, of the Institutes to investigate the philosophy of mind beyond those physiological considerations which are relative to the properties and functions of life, however it may have been important to their interests to contradistinguish the Maker from His works (§ 14 c, 175, $350\frac{a}{4}$ h-l). Perception and the will are the only mental properties which concur, more or less, in the

phenomena of animal life.

242. Perception is always necessary to true sensation, and therefore to the exercise of all the senses. The mind, or instinct, must perceive an impression made upon sense, and consciousness must operate before the impression can be realized. The phenomena of sympathy in their connection with sensibility, in the ordinary processes of life, are not relative to sensation, but depend on a special modification

of sensibility and on the nervous power.

243. The will, another property of the mind, upon which volition depends, exemplifies yet farther the complexity of the principles which obtain in the animal kingdom; and its phenomena admonish us to pause over that materialism which sees nothing but the demonstrations of physical and chemical power in the equally unique manifestations of irritability, sensibility, mobility, the nervous power,—the

entire organic force (§ 215).

The will presides in animal life. It governs the movements not only of the voluntary muscles, but even the operations of the other mental faculties. In producing muscular motion, the operations of judgment and perception are often associated, and even bring the will into action. All muscular movements with which the mind, or instinct, is not connected, depend upon other causes than the will. Voluntary motion is, therefore, as dependent on the will as true sensation is upon perception (§ 1072, b).

The will has very little operation in organic life (§ 500, e); though the passions operate with power upon the heart, the abdominal viscera, &c. This peculiarity is founded in consummate Design; since greater latitude to the will would be incompatible with animal existence; while, on the other hand, other elements of the mind are allowed, for useful purposes, to stretch their influences to the deep recesses of life.

244. The will, a property of the mind, like the nervous power a

property of the vital principle, is, therefore, a vital stimulus to the brain, whose chief office is the production of voluntary motion, by

bringing into action the nervous power.

245. When the will gives rise to voluntary motion the philosophy is the same as when motion is developed in the organs of organic life by the nervous power (\S 205–215). The latter may take place through impressions transmitted to the nervous centres (\S 227, 500), or by impressions exerted in a direct manner upon these centres (\S 227, 230, 477). The will operates in the direct manner, develops the nervous power, and transmits it to the irritability of the voluntary muscles, by which mobility is brought into operation (\S 233). When the passions affect the movements in organic life it is exactly in the same way as with the will in animal life (\S 500 h, 1040, 1072 b).

246. Thus it appears that the unity in the great plan of the nervous power, in its relations to both organic and animal life, to mind as well as to matter, and the perfect concurrence of all the facts, and the obvious nature of the whole, which declare a harmony of principles and laws throughout all the immense variety relative to the nervous power, continue to unfold a grandeur of the subject which invites an unprejudiced attention to the expositions I have made of this brilliant

institution of Nature (§ 1069–1082).

FOURTH DIVISION OF PHYSIOLOGY.

FUNCTIONS.

247. Our fourth grand division of Physiology comprehends the functions of organic beings. They are carried on by the properties of life in their connection with organized structure (§ 170, 175, 177), and of which the functions are the great final causes, or effects (§ 176). They are, indeed, the only useful ends of life; since, otherwise, all organic beings would exist in the condition of the seed and egg (§ 235, 236). The terminating series of the capillary vessels are the immediate instruments of all the essential processes in organic life, and therefore, also, of all diseases (§ 109, 410, 411, 668, 679).

248. The functions are common and peculiar.

249. The common functions belong to all organic beings. They consist of, 1st. Motion; 2d. Absorption; 3d. Assimilation; 4th. Distribution; 5th. Appropriation, or nutrition and secretion; 6th. Excretion; 7th. Calorification; 8th. Generation. The first seven are indispensable to animals and plants. The eighth appertains only to the species, and has no essential part in the organic economy (§ 97, 118-123, 153-156, 237, 578).

250. The peculiar functions belong to animals only. They are, I. Functions of relation; comprehending, 1st. Sensation; 2d. Sym-

pathy, or reflex nervous action.

II. Voluntary motion, and functions by which the mind and instinct act on external objects.

III. Other mental and instinctive functions.

I. COMMON, OR ORGANIC FUNCTIONS.

251. Organs which perform similar functions are very variable in structure in different orders of animals. The liver, for example, "is represented in one case by simple cæca, or blind sacs; in another by tufts of cæca; in a third by bunches of cells; in a fourth by a spongy mass; in a fifth by branched ducts ending in feather-like terminal twigs;" and so on, up to the complication of the most perfect animals. Nevertheless, they all secrete a very analogous fluid. And so of other organs and functions.

A due regard for the preceding facts must unavoidably reconcile every mind to what I have said as to microscopical explorations of the

minuteness of structure (§ 131, 304, 306, 409, e).

252. Though structure be very various, there is a great analogy in the vital functions and their immediate products,—even between plants and animals. This is remarkably true of every individual part in the different races of animals, whatever its simplicity or complexity (§ 251). Hence, it becomes more and more manifest that the properties of life have a greater agency in the formation of organic products than the structure itself (§ 67-69).

1. MOTION.

253. Motion is the immediate result of the action of mobility or contractility, and was necessarily explained in describing that property (§ 205-215). It is the function by which all things acquire their movement in organic beings.

254. Motion may be remotely mechanical, as the movement of the blood, ingesta, &c.; but the power and the actions of parts which gen-

erate the mechanical movements are purely vital.

255. Motion belongs, of course, to every tissue in which its manifestations occur; and it is therefore an error, however common, to limit this function to the muscular tissue.

256. The great offices of motion in organic life are to supply the system with useful materials, and to remove such as are useless.

257. In animal life this function appears under the aspect of locomotion or some analogous result, and I have associated the consideration of this modification of the function with that which is common to the organic life of animals and plants, on account of their common nature.

258. Voluntary motion proceeds from the action of the will upon the great nervous centre, by which the nervous power is developed and transmitted to the irritability of the voluntary muscles (§ 188, 208, 233, 476 c). Here the excitation of the nervous power is direct, as in the experiments by Wilson Philip (§ 486, 487). If the motion be involuntary, as in the ordinary movements of respiration, the development of the nervous power is indirect, according to the usual process when organic actions are influenced by the nervous power (§ 222, &c., 500). When other involuntary motions affect the muscles of animal life, as convulsions, &c., the development of the nervous power may be direct, as in diseases, and concussions, of the brain, or indirect, as in teething, and intestinal irritation. The philosophy, however, respecting the production of motion in all these cases, is exactly the same. Whether the movements be voluntary or involuntary, the

movements depend upon the action of the nervous influence upon mobility through the property irritability. The mind does not, as has been supposed, leave the brain to enter the muscles in voluntary motion. The difficulties of explanation are not only multiplied by this supposition, but it is shown to be erroneous by the analogous movements which may be excited through the spinal cord, or through the nerves, after the soul and instinctive principle are separated from the body by the removal of the head. This philosophy is also coincident with that which I have propounded as to influences of the nervous power in organic life. Each illustrates and sustains the other (§ 500).

259. It is now important to repeat, that the nervous power never generates motion, per se (§ 222-232). The function always depends immediately upon the organic property mobility, which is brought into action through impressions made upon irritability (§ 188). The nervous power is only a stimulus to irritability. But, it is much more important to motion in animal than organic life; since it is the only natural stimulus of the voluntary muscles, while blood, and other agents, operate upon the tissues with which they are in contact in organic life, and thus excite reflex nervous actions, and render them tributary as an exciting cause of muscular motion and in increasing or diminishing and otherwise affecting the secreted products (§ 224, 226, 475½, 893½).

260. Very important laws grow out of the foregoing distinction between the relation of the nervous power to the function of motion in animal and organic life, and its essential independence of that power

in either life ($\S 475\frac{1}{2}$, 476, 498, 500 m, $893\frac{1}{2}$, 1042).

261. That motion does not depend upon the nerves is shown by the sensible and insensible motions of plants; by that of their leaves, stems, stamens, by their absorption, nutrition, secretion, &c. (§ 455, c). The analogies in results prove this independence of the nerves, and the near identity of the function in plants and animals. Indeed, the chemists will have it that all the essential compounds of the animal are formed by vegetable organization (§ 18, 409). Such analogies are always sound, being based on great fundamental laws. But there may be great variety of mechanism. Where nerves exist, and in connection with centres capable of generating a stimulus, they are so far tributary to muscular and other motions, and voluntary motion is wholly dependent upon that stimulus, as also natural involuntary muscular motion.

262. "The heart of a frog continues to beat with its ordinary rhythm even when the entire base of the organ, when the ventricles, as far as their juncture with the auricles, are cut away" (p. 346, \S 516 d, no. 8).

In the same way, "the peristaltic movements of the intestinal canal continue not only when the intestine is removed from the trunk together with the mesentery and ganglionic plexus, but also when the intestine itself is isolated from the plexus by being separated from the mesentery at the line of its insertion."—MULLER'S Physiology.

263. Dr. M. Hall tied a ligature around the root of the heart and lungs, and then separated them from the body. "The action of the heart was still such as to carry on, in a slight degree, and for a short period, the circulation of the blood through the pulmonary artery, and a few of the capillary vessels." He adds his belief, "that the actual circulation of the blood has not been before seen proceeding entirely and independently of the sympathetic system."—HALL.

264. Now, in the last two of the foregoing cases there may have

been local nervous centres, ganglia, perhaps, or some other part of the sympathetic nerve to supply the requisite stimulus through reflex actions; the air and the injuries operating as remote exciting causes of the nervous influence (§ $475\frac{1}{2}$). But in the case of the mutilated heart the nature of the injury precludes the supposition that there could have been any radiating focus of reflex actions, which is probably equally true of the case in § 498~e; so that in those instances the air and the mechanical irritation were alone the exciting causes. Note A p. 1111.

265. Motion, therefore, whether voluntary or involuntary, is carried on through properties inherent in the various tissues, and the nervous influence is only a remote exciting cause, and in that respect on common ground with other vital agents, while also, as will be seen, it is an indispensable regulator of the organic mechanism of animals, and tributary to the perfection of their organic compounds (§ 222-233\frac{4}{5}, 500).

266. The nervous power, in developing motion in either organic or animal life, as a stimulus to the organic properties, does not follow the nerves according to their regular order of distribution from the nervous centres. On the contrary, its entire want of uniformity in that respect—operating simultaneously, at one time, through a nerve or nerves proceeding from the cranium and some inferior part of the spinal canal, while it passes over all intermediate nerves—or, at another time, electing, without any regularity in respect to order of arrangement, two or more of those intermediate spinal nerves—this entire want of respect to anatomical order is so familiar to all that it has not appeared as one of the most difficult and sublime problems of This very extraordinary attribute of the nervous power is rendered the more remarkable by our knowledge of the fact that its operation is determined through particular nerves either by an act of the will, or, in organic life, by particular passions, by their intensity of operation, and by the special nature and intensity of physical agents which may transmit their influences to the nervous centres through some other part; and, in the cases relative to organic life, according, also, to the existing susceptibility of the various parts of the organism (§ 137 d, 143, 148–152, $233\frac{3}{4}$, 500, $892\frac{1}{2}v$, 893, 905, 1059).

267. All the foregoing are established facts, of perpetual occurrence; and they should be taken in connection with the doctrines which I have advanced as to artificial modifications of the nervous power, and the modus operandi of morbific and remedial agents (\$ 224-233\frac{4}{5}, 497-500,

503, 506, 889 a, $891\frac{1}{2}$ k, 892 aa, 893–905).

2. ABSORPTION.

268. Absorption is performed, in animals, by the lacteals and lymphatics; those vessels being very similar in their constitution and function. There are corresponding means for the office of absorption

in the roots and leaves of plants.

269. Magendie, and others who have copied from him, have fallen into the error of attributing the office of absorption to the veins. He was led into the mistake by an ignorance of the fact that the lymphatics terminate variously in small veins.* Fallacies of that nature should be apparent upon principle alone—at least to such as recognize a unity of design, and a simplicity in the great institutions of nature. Every system of vessels, so far as known, has but one func-

^{*} See Medical and Physiological Commentaries, vol. ii., p. 170, note, 380, 394-396.

tion, however that may be modified in different parts, as seen in the lymphatics and lacteals, in the terminal series of the capillary arteries in all parts, &c. The distinction depends either upon structure connected with the modifications of common vital properties, and their relative adaptations to the physical properties of different fluids, or, structure may be apparently less concerned than the organic properties; which is one of the most universal and important principles in physiology (§ 133–150).

270. The lacteals perform the office of absorbing, and introducing

into the organization of animals, foreign nutritive matter.

271. The lymphatics, in greater part, are destined for the vital decomposition of the body, and for the removal of waste parts, which are conveyed by the lymphatics into the torrent of blood to be ultimately cast out of the system, or again to undergo, in part, the process of sanguification. May absorb from surfaces, but not nutritive matter.

272. By these vessels, also, the solids are removed in the ulcerative process of inflammation, and mortified parts are detached from the sound,* and foreign substances which are introduced into the body are

taken up and removed.

273. Hence it is obvious that the lacteals and lymphatics are antagonizing systems, and that beings so endowed are the constant subjects of waste as well as of nutrition; the balance being maintained through the inlet supplied by the lacteals, and the outlet provided by the lymphatics (§ 180-182, 286). Notwithstanding, therefore, the coincidence in the general function of these two systems of vessels, the office of one is creative, that of the other destructive.

During the period of growth nutrition overbalances waste; but, when growth ceases, nutrition and vital decomposition must be in

equilibrio.

274. No substances but such as exist in a fluid or very attenuated

state are taken up by the lacteals and absorbents.

275. The intestinal villi have been shown by Cruikshank, Bleuland, and others to possess open orifices,† though this is denied by the microscopists; and I have shown that the modifying influence of the ganglionic nerves upon all the organic functions and products contradicts the hypotheses of catalysis and endosmose and exosmose (§ 1089).

276. Different substances are absorbed with various degrees of rapidity, both in animals and plants. This depends on their peculiar virtues, and on the manner, therefore, in which they affect irritability; thus showing the vital nature of the process (§ 149, 188, &c., 207). The same conclusion is also inferable from experiments, as well upon

plants as animals.

277, a. Again, the lacteals, in virtue of their special modifications of irritability, exclude every thing but chyle. Bile is not taken up either by the lacteals or lymphatics; cathartics pass off; emetics are The principle is every where; is shown in the larynx, pylorus, &c., in the sparseness of the red globules in the lymph vessels, though their diameters be many times larger than the globules of blood (§ 399). The principle lies in the virtues of the agents and the special modification of irritability which belongs to each part (§ 135). It is designed for the conservation of every part, and of the

^{*} See Med. and Physiolog. Comm., vol. ii., p. 168, 169, 171–173. † Ibid., vol. i., p. 683–690, 699–712.

whole. Had not the lacteals and lymphatics been endowed in this wonderful manner, or were absorption a mere physical process, or capillary attraction, or endosmose, all foreign substances would have free access to the internal parts of the organization, and organic beings would have had no continued existence. They would have perished as soon as created. Hence, are the vital properties so modified in all these millions of inlets into the labyrinth of organization that they shall be not only vigilant sentinels, but recognize, at once, every one of the thousand offenders that may endeavor to steal its way into the sanctum sanctorum (§ 192).

277, b. Some of the most important laws in medicine are founded on the special modifications of irritability in different parts (§ 149, 150); and as it respects the lacteals and lymphatics, the principle not only contradicts the assumption of the operation of medicines by absorption,

but confirms, in a beautiful manner, the laws of sympathy.

278. It is only when the lacteals and lymphatics become morbidly affected, or their irritability essentially modified by the morbific action of agents offensive to the organization, that those agents are at all admitted, and then only very sparingly. The principle is the same as when undigested food escapes the pyloric orifice in indigestion, or the red globules of blood gain admittance to the serous vessels in inflammation (§ 14, 74, 117, 137, 143, 155, 156, 169 f, 266, 303\frac{1}{4} a, 306, 310, 313, 325, 387, 399, 409 f, 422, 514 h, 524 d, 525, 526 d, 528 c, 638, 649 d, 764 b, 811, 847 c, 848, 902 f, 905).

279. If, therefore, foreign agents affect the absorbent vessels in the foregoing manner, so also do they affect the condition of the other tissues of the part. This is the beginning of disease, which may now go on accumulating without any farther agency of the exciting cause; or, if the offending cause gain admission into the circulation, it may continue, per se, to exasperate disease. But, even in this case of the continued operation of morbific or remedial agents after their absorption, I have shown that solidism and vitalism can alone explain their effects (§ 819, &c.).

280. I have also shown that when morbific or remedial agents are taken into the circulation the quantity is so small, their dilution by the blood and other fluids so great, and their elimination by the kidneys so rapid (at least in a general sense), that little or nothing is likely to be contributed in this way to the morbific or remedial effects.

The rapidity with which agents that are not morbific, but useless to the system, are elaborated by the kidneys, is a proof, upon the principle of Design, that a provision exists for the exclusion of deleterious agents from the circulation. But, since they may, under special circumstances, pass the great sentinel (§ 278), the kidneys are provided as other guards to the general organism, to expel the offenders at once. Just so with the lungs. If offensive objects pass the larynx, all the muscles of respiration, through a beautiful system of Design, immediately set at work to get rid of the intruder. The intelligent reader will readily carry this principle to more recondite processes, as the institution of abscesses, and the curious steps that attend their progress from deep-seated parts toward the surface (§ 733).

281. It may be also added, that I know of no critical attempt having been made to invalidate the facts and the reasoning set forth in my Essay on the Humoral Pathology, which has for its object the ex-

posure of that pathology and the defense of solidism and vitalism; and, although that work has been now six years before the public, I know not that I have omitted the investigation of one essential fact or experiment that has been alleged or instituted in behalf of humoralism.

If such omission has occurred, let it be shown.*

282. Many distinguished men have been led into the error of sup posing that noxious substances are taken readily into the circulation because the skin is deeply tinged with yellow, in jaundice; or because the bones become red when madder is eaten; or the urine is colored by rhubarb, or manifests the odor of turpentine, of garlic, &c. But, let it be considered, that the inoffensive coloring matter of the bile is alone absorbed, as is also that of madder and rhubarb, &c.; while the thousandth part of a grain of spirits of turpentine, or of garlic, is enough to impart all the odor to the urine that has been ever observed to attend that product.

283. If remedial and morbific agents be absorbed, it devolves upon the mechanical philosophers to show the fact, which they have failed of doing in regard to many of the most important (§ 826 c); but should their assumptions become realities, I shall have demonstrated by a multitude of analogies where absorption is out of the question, and in various other ways, that the *modus operandi* of the whole rests upon the

philosophy of the natural physiological laws (§ 1088-1089).

284. Although a very limited operation of morbific and remedial agents, through their absorption into the circulation, be not incompatible with solidism and vitalism (§ 277, 278, 283, 827 f), the usual interpretation of their effects, according to the doctrines of humoralism, would compel us to abandon the application of physiology to medicine, whether pathologically considered, or in respect to the operation of curative agents. The laws of disease would be totally unlike the laws of health; or, rather, disease would be without laws, and there would, therefore, be no general principles in medicine. Practice would be a blind empyricism. Diseases would be just as various and uncertain as every chemical change in the blood, and these changes, upon the ground of humoralism, would have no resemblances to each other.

285. The properties of life lie at the foundation of physiology. It is a knowledge of their character, and of the laws which they obey, that enables us to conform our habits, at all ages, in the best way for the maintenance of health. But, what is disease? It is a deviation from the state of health; and, therefore, if there be any consistency in nature, disease should consist primarily and essentially in modifications of those vital properties, which, in a different state, constitute the important conditions of health. In this way, therefore, medicine takes the rank of an intelligible and important science. Physiology is the ground-work throughout. Pathology becomes nothing more than physiology modified. And, coming to therapeutics, it is still physiology applied to the cure of diseases; or, in other words, the application of such agents to the morbid properties of life as shall aid their restoration to their natural physiological state. The whole is thus bound together. No new elements come into operation; but, throughout the whole series of changes, the same powers are in action and carry on all the processes. Nor are there any new laws intro-The powers and actions being fundamentally the same, *In Medical and Physiological Comm. vol. i. 1840 .- Now 25 years, and no attempt made. -1865.

so are the laws, of health and disease, as are those, also, by which diseased are converted to healthy conditions. But, the powers or properties of life being modified in disease, and again modified in other ways by the action of remedial agents, so are the laws, under which all these results happen, varied in a corresponding manner. The laws are only the conditions under which effects take place; and, as those effects have always a direct reference to the state of the vital properties, they must be fundamentally of the same nature under all the various conditions of life, since, also, the vital properties never lose their fundamental character (§ 1, 639).

286. When, therefore, I may speak of the laws of health and the laws of disease, I must not be understood as meaning something entirely different in the two cases. And yet, their modifications are always precise, and the results of each are always determined in one uniform manner. This is necessarily so, because the changes in the vital properties are always precise, and according to the nature of the in-

fluences by which the changes are effected (§ 149, 150).

287. In this sense, therefore (§ 286), the laws may be assumed to

be, in each individual modification, of a specific nature.

288. Laws may be said to be general and specific; which, however, is only another mode of considering the foregoing principle (§ 285). Thus, it is a general law that the absorbents, whether in health or disease, do not take up foreign substances of a deleterious nature; but, it is a specific law, that when the irritability of the lacteals or lymphatics is modified in a certain way, they will admit a small proportion of the noxious agent by which the alteration is produced (§ 277, 278).

289. Those mechanical physiologists who have not, or will not have, just conceptions of the properties and actions of life, refer the process of absorption to capillary attraction, or that mechanical principle which determines the ascent of oil in the wick of a lamp (§ 277). The chemists belong to this class of reasoners; even such of them as allow the existence of a vital principle. Thus, for example, Liebig has it,

that,

"A cotton wick inclosed in a lamp, which contains a liquid saturated with carbonic acid, acts exactly in the same manner as a living plant in the night. Water and carbonic acid are sucked up by capillary attraction, and both evaporate from the exterior part of the wick." Again, "All substances in solution in a soil are absorbed by the roots of plants exactly as a sponge imbibes a liquid, and all it contains, without selection."—LIEBIG'S Organic Chemistry applied to

Physiology and Agriculture.

Now all this might be very good philosophy for a common agriculturist; but it evinces an unaccountable disregard of facts, and of the plainest suggestions of nature. And yet it is a common doctrine now-adays; a part of the "new experimental philosophy." In the first place, however, it is not true that the roots of plants imbibe their nourishment "without selection." When plants are cultivated in glass vessels containing distilled water, their roots will even decompose the glass, and select its silica, or alkali, or take them both, and assimilate them to themselves, and in the absence of any known chemical affinities or influences. Absorption is nearly as exact in plants as in animals; and so is a propriation. Like animals, their absorbent system

is naturally repulsive of every thing that is offensive and not suitable to their economy. If poisons, when artificially applied, get admission, it is by inflicting a violence on the radicles of plants (§ 278). And what is thus prompted by reason, by analogy, by common experience, is fully confirmed by the chemists themselves, in those analyses of all parts of a plant, even the sap, which are designed as standards of the composition which shall serve for any particular part of any given species of plant, as well through all future time as at the hour when

the analyses were made (§ 1052, 1053, 1054).

290. The simile of the "lamp-wick," and of the "sponge" (§ 289), show us how far astray our friends are from the path of truth. It is not alone the complex mechanism of the root which the absorbed materials traverse, but a labyrinth of highly organized and living tubes, passing through the whole trunk of the plant, till the materials finally reach the leaves. In those respiratory organs, the pabulum vitæ is farther subjected to the action of another complicated, unique, and living system of vessels. And what is the "wick of a lamp?" A mere bundle of dead, disorganized fibres, broken upon the card, and spun upon the wheel (§ 350½ n, o, 826 c).

291. But, the foregoing degrading doctrine of life (§ 289) is not peculiar to the chemists. Some reputedly profound physiologists apply it not only to plants, but to animals, and, like Liebig, identify the same vital and physical processes. One example, in a distinguished

quarter, will suffice. Thus, Dr. Carpenter:

"It will be hereafter shown that the absorption of nutritious fluid is probably due to the *physical* power of endosmose. A continued absorption may be produced by a *physical contrivance which imitates* the effects of vital action; [!] as in the wick of a lamp, which draws up oil to supply the combustion above, but will cease to do so when the demand no longer exists"! (§ 64 g, 175 d).—CARPENTER'S Comparative Physiology.

The work, a standard one, from which the foregoing is quoted, abounds with analogous doctrines. They are, of course, fatal to

physiology and to all medical science.

292. Immediately after the quotation from Liebig, in the preceding section, that author proceeds to reprobate physiologists for their exclusion of chemistry from organic life, and charitably regards it as a prejudice arising from our ignorance of the science (§ 350, a). This, however, is quite an untenable position; for, wherever medicine is cultivated chemistry is justly made a fundamental part of education. It is, indeed, the knowledge which the soundest physiologists possess of chemical science that enables them to institute the necessary contrasts, and which convinces them that chemistry, in its proper acceptation, has no connection with the processes of living beings. This, indeed, I have abundantly shown to be the real opinion of the chemists themselves (§ 350, &c.). Bold in assumption, inapt in illustration, and, at last, like Liebig, contradicting the whole by an acknowledgment that "vitality, in its peculiar operations, makes use of a special apparatus for each function of an organ," and that "in the living organism we are acquainted with only one cause of motion; and this is the SAME CAUSE which determines the growth of living tissues, and gives them the power of resistance to external agencies. It is THE VITAL FORCE."—LIEBIG (§ 350, nos. 26, 27, 28, 71-77, &c.).

293. Looking at other facts attending the process of absorption in plants, we shall find them all concurring with what I have already stated as to the dependence of this function upon vital actions; and, if vital here, we need not look for other proof of a similar law in animals. Thus, Van Marum demonstrated that absorbed fluids could rise only eight inches by capillary attraction. Hales, Walker, Mirbel, Chevreuil, and others, have shown that the sap moves with such velocity and force in plants, that it must be propelled by vital contractions and dilatations of the vessels. We have examples of this surprising rapidity of the circulation in grape-vines. Don and Barbieri affirm that they saw the movements of the vessels.

Again, the motion of sap is increased by light, heat, and other stimuli, which have no effect on capillary attraction. And this is the opinion even of Liebig, who says that "the functions of plants certainly proceed with greater intensity and rapidity in sunshine, than in the diffused light of day; but it merely ACCLERATES in a greater degree THE ACTION ALREADY EXISTING;" "an action," he says, "which de-

pends on the vital force alone."

It was shown by La Place, that, if the sap rose by capillary attraction, it should not, as it does, flow from the openings made in the vessels. But, again, the sap will not flow from the openings, if the plants be poisoned with prussic acid. The effect is the same as upon the circulation of the blood; and it would be equally absurd, in either case, to suppose that the poison acts upon any physical force. Astringents, and various other substances, applied to the openings, avert the flow of sap, which can only be done through the foregoing principles (§ 278–384, 1054).

294. Here is another fact, and which appears to be conclusive of the vital nature of absorption, and of the discrimination observed by the radicles of plants (§ 289, 291). It is, that the sap of the root is unlike any thing which it absorbs from the earth. All the substances are decompounded at the moment of entering the roots, just as the carbonic acid is by the leaves. Their elements are then also united according to the modes which prevail in organic compounds (§ 38, 42).

295. Equally unfounded as the doctrine of capillary attraction are the supposed processes of endosmose and exosmose. They are generally predicated of experiments upon dead matter, and are then carried, by way of analogy, to the living organism, and in defiance of all the contradictory phenomena of life.* Having entered extensively into a refutation of the hypothesis of endosmose and exosmose in the Medical and Physiological Commentaries, I shall not now resume the subject (§ 1052, 1053, 1054).

3. ASSIMILATION.

296. By the function of assimilation substances taken into the body are converted into the homogeneous blood, and identified in composition and vital properties with all parts of the body. It is therefore especially concerned in the process of growth, and in supplying the waste which is constantly in progress. It is the function, therefore, by which the properties of life are communicated to dead matter.

297. All dead matter, before its reception into the body, is subject to the forces of chemistry. The operation of these forces is arrested in the alimentary canal of animals, and in the absorbing vessels of plants.

^{*} Violence is inflicted in the experiments upon living tissues.

298. The nutriment of vegetables consists always of inorganic sub stances, or is reduced to the condition of inorganic matter before its appropriation. The food of animals is always organic. The former exists in an elementary or in a state of binary combination, the latter of ternary, quaternary, &c. It is the work of vegetable assimilation to overthrow the chemical combinations, and to unite the elements in those very different modes which constitute organic compounds. This is the most remarkable and comprehensive System of Design of which we have any knowledge (§ 1052).—Notes NR pp. 1121, 1123.

299. Assimilation, therefore, devolves especially upon the properties vivification and vital affinity (§ 216, 218); though it be certainly true that all the organic powers and functions are necessary to each other, and concur together in producing every result. But, in every

result there are some more interested than others.

300. Animals, being incapable of organizing inorganic substances, are dependent upon the vegetable kingdom as their ultimate source of supply (§ 13, 14). Such, indeed, is the final cause of vegetable life. But the food of animals must be dead before it can begin to undergo the action of the vital properties in another being. The gastric juice, for instance, has no effect upon any living substance.

301. No organic compound ever undergoes chemical decomposition, or any approximation toward such decomposition, to fit it for the purposes of animal life. On the contrary, every such tendency places the appropriate nutriment of animals, more or less, beyond their assimilating endowments. It is the province of animal life, and of all its provisions for assimilation, not to carry back toward their inorganic condition the peculiar compounds generated by the vegetable kingdom for the foreordained uses of the animal, but to carry them forward to yet higher degrees of life and organization. This is one of the most fundamental laws of nature, and is conclusive against all the chemical speculations with which physiology has been so unhappily visited (§ 356 b-376).* The argument belongs to me (§ 1084).

302, a. The assimilating organs in vegetables are more simple than in animals, and the complexity increases in animals according to their rank in the scale of life. It would appear, therefore, that organization bears a ratio more or less proportionate to the endowment of organization.

ganic compounds with the properties of life (§ 301, 409).

302, b. The process of converting inorganic into organic compounds begins in two orders of vessels, one of which are the radical absorb-

ents of plants, the other analogous vessels in the leaves.

The matter absorbed by the roots ascends through the stem to the leaves, where, by the operation of a series of vessels, variously modified in different species, it is converted, along with that absorbed by the leaves, into a juice, which, like the blood, is thus fitted for the purposes of nutrition. This juice then descends through other vessels, to be appropriated to all parts, and to form the source of all the various products of vegetable organization.

303, a. We come, therefore, to a conclusion as remarkable as it is comprehensive, that the atmosphere is not only essential to plants and animals in its usual acceptation, but that it supplies the great means of nutriment to both organic kingdoms: directly to the vegetable, and indirectly to the animal department (§ 298–300). Mineral compounds appertaining to the earth must yield the less important elements, and

^{*} Chemists are beginning to adopt this conclusion, as appears in Note at p. 196.—1860.

even some proportion of oxygen through the decomposition of rocks and metals and the appropriate combinations that may ensue; but we must look especially to the atmosphere and what it contains for the four great elements which compose organic beings. The oxygen and the nitrogen of the air, the oxygen and the hydrogen of the vapor which the air contains, and the carbon of the carbonic acid, are as much at this day the great source of nutriment to plants, as before the "mist" went up from the seas, or animals yielded ammonia. Oxygen and nitrogen, therefore, as it respects atmospheric air, are appropriated by plants in their elementary condition. Upon organic compounds thus formed is animal existence, in the main, dependent. Ammonia certainly contributes to the nourishment of plants. But this is an incidental means, at least if there be any truth in Moses. And that his Record is true, is plain enough upon the principle of Design; since it is impossible that Providence should have created the animal kingdom, which yields the ammonia, before he brought forth that kingdom upon which animals depend for their existence.

303, b. As it respects absorption, the leaves and the roots of plants appear to have a common office, though the former are designed especially for assimilation. The carbonic acid, and the oxygen and the nitrogen of the air, are precipitated along with the vapor, and thus reach the organs which are principally devoted to absorption. In no other way can we primarily reach the materials of all organic beings. Before their absorption can have begun, the most essential elements must have been embraced originally in the atmosphere, and in the simple conditions which I have stated. Nor is it a difficult process to follow out that circuit of causes and effects in which revolves the economy of nature in making the waste of organic beings during their own existence a subsidiary supply of nourishment to themselves, or to others of their own day, or to generations in the womb of time; or, when consigned "to the dust," how their elements, from one generation to another, form an endless round of materials for reproduction and growth, either in the form of gases and vapor diffused in the air or as imbodied with the earth.

303, c. Although it be the special object of the radical fibres to carry on the function of absorption, this office is more or less performed by the leaves of plants, but in various degrees, according to the nature of the species. In arid climates, the leaves have this function strongly pronounced; and many plants, like the sempervirens, will grow as well when suspended by a string, as when connected by their roots with the soil.

303, d. The leaves of plants absorb carbonic acid mostly during the day, decompound it through a vital process, and otherwise prepare it as an important source of nourishment. Light is necessary to this function of the leaves, and without it the plant languishes and dies. As an attendant result oxygen gas is evolved into the atmosphere. The process is, therefore, suspended during the absence of light, and some proportion of carbonic acid is regenerated and escapes along with the vapor which is exhaled by the leaves. It has been also supposed that more or less oxygen is absorbed at night; but this opinion appears not to be sustained by later and better observations. It is most probable, indeed, that the temporary absence of light occasions scarcely more than a suspension of the assimilating process. Light acts as a vital

stimulus to the leaves, by which their organic properties are rendered capable of overthrowing that most refractory compound, carbonic acid

 $(\S 188\frac{1}{2} d, 350, \text{ nos. } 64, 66, 68-76,)$

303, e. The leaves of plants being the great organs of assimilation, and light the vital stimulus by which the function is maintained (\S 188 $\frac{1}{2}$, d), it appears from what has been now said that light holds the first rank among the requisites of life. It was therefore brought into existence before the creation of the vegetable kingdom; and being thus indispensable to all living beings, we see the fallacy of a common tenet in theoretical geology, that the most thrifty period of vegetation was through a great cycle of total darkness, and an atmosphere of

carbonic acid (§ 74, 1079 b).

3031, a. One of the most interesting facts in vegetable physiology is the immediate necessity of plants to animal life during their very growth; their final cause, in this respect, being the abstraction of carbonic acid from the atmosphere, and the renewal of its oxygen. Animals, too, as we have seen, incidentally contribute carbon to the vegetable kingdom, in the form of carbonic acid, and nitrogen in the form of ammonia. There is this remarkable subserviency of the organic kingdoms to each other, though there be not a reciprocal dependence. Vegetables, indeed, preceded animals, and are, therefore, essentially independent, while animals derive all they possess from vegetable creation (§ 303, a). Plants are the producers, animals the consumers. The former directly, and the latter indirectly, live upon the air and what it contains. The plant dies and becomes food for the animal; but it seems scarcely less important in its living state to the exigencies of animal life. And so the animal, living and dead, yields back its all to the atmosphere; and thus are the inorganic, and the two departments of the organic, kingdoms united (§ 1052, 1053).

 $303\frac{1}{4}$, b. But, we have seen, as I originally indicated in the Essay on the *Philosophy of Vitality*, that the supply of ammonia to the atmosphere is only a contingent result of the creation of animals, and there fore not indispensable to vegetation (§ 156 b, 303 a). Liebig, how-

ever, reverses the order of Creation, and affirms that

"We have not the slightest reason for believing that the nitrogen of the atmosphere takes part in the process of assimilation of plants and animals." "These facts are not sufficient to establish the opinion that it is ammonia which affords all vegetables, without exception, the nitrogen which enters into the composition of their constituent substances. Considerations of another kind, however, give to this opinion a degree of certainty which completely excludes all other views of

the matter."—Liebig's Organic Chemistry, &c., p. 70, 71.

303\frac{1}{4}, c. The same mistake has arisen with the chemists as to the reciprocal dependence of animals and plants, in regard to the excretion of carbon by one and oxygen by the other. However true it may be that animals are dependent on plants for oxygen gas, it is certainly an assumption that the vegetable kingdom is alike dependent on the animal for its carbonaceous element. If the primary creation of plants be admitted, that is sufficient; and to those who reject the Mosaic Record, and the concurring testimony of geologists, I may repeat the admitted fact that vegetables are the ultimate source of supply to all animals. The former, therefore, are essentially independent, the latter dependent; while this universal fact corroborates, also,

the original account of the primary creation of the vegetable kingdom

(§ 303½).

As to the relations of the living plant to organic life, it is computed by Saussure, and allowed by others, that the atmosphere contains about 1000 th part of its weight of carbonic acid. The atmosphere must be also losing, through the processes of respiration, combustion, &c., a proportion of its oxygen. It is estimated, also, that the present number of human beings would, alone, double the existing quantity of carbonic acid in the air in 1000 years; and, in 303,000 years would exhaust its oxygen. It is also found that atmospheric air of the present day does not contain less oxygen than that which is found in jars buried for 1800 years in the ruins of Pompeii.

From all this it is inferable that there is a universal cause in operation, by which the carbonic acid of the air is consumed, and oxygen supplied; and, from the various well-known, and indispensable uses of the vegetable kingdom to the animal, which declare its creation for the benefit of the latter, and, therefore, its antecedent or simultaneous creation, we should naturally be prompted, by analogy, to look to this subordinate provision as the universal source through which the great purposes of respiration are maintained unimpaired. Chemistry has here elegantly illustrated this great element in the final causes of the vegetable kingdom, and the contingent aid which it derives from the animal; while it enlarges our view of the vast conceptions of Unity of

Design.

 $30\overline{3}\frac{1}{2}$. It is also worth our while to observe of these important laws, as we go along, how they are perverted by the ignorant in physiology, and how incapable the chemist is constantly proving himself of pursuing his reasoning," as said of him by Hunter, "even beyond

the simple experiment itself."

Vegetables, as we have seen, are composed mainly of carbon, oxygen, hydrogen, and nitrogen (§ 37, 303). The carbonic acid of the air (as well as of the soil) is absorbed by plants, and appropriated to their nourishment and growth. This gaseous substance, therefore, is decomposed by vegetable organization, the carbon vivified and appropriated, and a part of the oxygen thrown off to replenish the atmosphere. It is incorrectly said, however, by Liebig, that "the atmosphere must receive by this process a volume of oxygen for every volume of carbonic acid which has been decomposed." It may be meant, however, that an equivalent or atom of oxygen for every equivalent of carbon is given off to the atmosphere; but even this construction is invalidated by the multiplicity of sources from which plants are supplied with that important element. But enough is known to render it certain that a large proportion of the oxygen of carbonic acid is retained by plants and combined under a new form along with the carbon and other elements. Liebig's hypothesis of capillary attraction led him, not improbably, to overlook the fact that the water which is absorbed by plants is actually decompounded, and its elements combined with others according to the laws which determine organic compounds. It is water, indeed, which yields, far more than ammonia, the hydrogen which abounds in plants (§ 303, b). Water, therefore, being composed of oxygen and hydrogen, furnishes a source of the supply of that oxygen which goes to the increase of vegetables; and, for aught that can be said to the contrary, it may form a part of what is evolved into the air.

We have seen, also, that plants derive a part of their oxygen from mineral compounds appertaining to the earth, and probably by means of the roots from the atmospheric air which is held in solution by water, when the gas may be thus appropriated, notwithstanding its elementary condition in the latter case. Although, doubtless, more or less carbonic acid is reproduced in the leaves and escapes at night along with the vapor exhaled, the probabilities are against the supposition that a proportion is also then generated and emitted by plants in a manner analogous to the respiration of animals, and having for its object, in part, the separation of carbon from some of the vegetable constituents.

3033. But let us come to philosophy:-

"At night," says Liebig, "A TRUE CHEMICAL PROCESS COMMENCES, in consequence of the action of the oxygen of the air upon the substances composing the leaves, blossoms, and fruit. This process is not at all connected with the life of the vegetable organism, because it goes on in the DEAD plant EXACTLY as in a LIVING one"!

Here, in the first place, is an important fallacy in the premises from which the induction is made; since the processes have not the least analogy in the living and dead plant. In the former, the oxygen is taken into the organization, and goes to form organic compounds. In the dead plant, it is an agent of chemical decomposition, by which the organic compounds are destroyed, and the structure broken up.

Now we shall always find that authors who reason in the foregoing manner perpetually contradict themselves. In the case before us, a contradiction necessarily arises from the fundamental differences between the processes of organic and inorganic beings, and the laws by which they are governed. A little farther on from the quotation I have just made, Liebig affirms that "the laws of life cannot be investigated in an organized being which is diseased or dying." Here, then, is a contradictory opinion, which inculcates as great an error in physiology as that of identifying the effects of oxygen on "living beings" and on such as are actually dead. Here is an absolute denial of any analogies between the laws which govern living "diseased beings" and the "laws of life." But, this declaration of the chemist, devoid of truth as it is, is universally applicable where he would be least disposed to see it operate. Such an application, too, is an irresistible sequitur; since, if "the laws of life cannot be investigated in an organized being which is diseased or dying," it certainly follows that the laws which relate to dead, or inorganic beings, and the forces upon which those laws depend, can have no agency in living beings.

Such, however, is the material which is now-a-days denominated "experimental philosophy," and "the progress of medical science." And, if the reader will now turn to the parallel columns (§ 350), he will see yet other contradictions directly relative to the foregoing

quotation (§ 1052, 1053).

But, it may, perhaps, be well enough, before dismissing this subject, to say, that, although "the laws of life cannot be investigated in an organized being which is dying," the laws which govern diseased actions and their results are only slightly modified "laws of life," and often reflect great light upon their strictly healthy condition. We are, or should be, constantly reasoning in this manner in all cases of disease; and it is only by comparisons of the modifications, which constitute disease, with the natural conditions of life, that we can have

any just knowledge of diseases. In proportion, however, as the individual approximates a state of death all this reasoning fails; and, when actually dead, no such comparisons can be instituted. Here, then, it is that the foregoing admission of the chemist applies with all

the force of truth (δ 639 a).

304. The greater complexity of the organs of assimilation in animal life gives rise to a variety of subordinate functions in animals not found in plants; such, for example, as digestion by the gastric juice, saliva, bile, &c.; then a farther advancement of the process in the lacteals, in the blood-vessels, in the lungs, &c. Some of these subordinate functions, however, have their analogies in plants; such as the action of the sap-vessels upon the circulating fluid, the imbibition and exhalation of gaseous substances by the leaves, &c. But, in all the cases, the extreme vessels which perform the office of nutrition are the main instruments of organic life. All the functions which are carried on by compound structures are subsidiary only to that of the nutritive vessels (§ 171).

305. The organs of assimilation in animals are more or less complex according to the nature of the food. Probably every animal has a stomach, or some analogous organ, and a mouth, and anus, which would form, as supposed by Aristotle, a fundamental distinction between plants and animals (§ 11). The analogies which are supplied by the higher orders of animals would prompt this conclusion in respect to the most inferior, or some equivalent arrangement.

306. In vertebrated animals the stomach is generally an expanded portion only of the intestinal canal. In fishes the intestine is commonly short; but this is often compensated by folds in the mucous membrane. In birds there is a complexity of the alimentary organs which does not exist in fishes, amphibia, or reptiles. In mammalia the digestive organization is still different; and here it is more remarkably various according to the nature of the food, and as the necessity of supplies may be felt at short or at longer intervals. The more, also, the phenomena of animal life are multiplied the greater is the development of the digestive system (§ 107, 251, 353). complex nature has an intimate relation to the qualities of the food, and these relations have an affinity with that principle of instinct which directs animals in the selection of food. The more dense and tough the food, and the more removed from the nature of the body which it is destined to nourish, the more complex are the organs of digestion. And so, on the contrary, the softer the food, and the more it is like the animal in its composition, the more simple are the assimilating organs. Animals, therefore, which live on hay have these organs much more complex than such as are nourished by animal food; especially that part of the organization which is destined to make the first and greatest change.

307. The principal agent in the assimilating process, in animals, is the gastric juice; a vital organic fluid, which is secreted by the internal coat of the stomach (§ 135 a, 316, 419, 827 b). This secretion is especially promoted by the stimulus of food, which is dissolved and altered in its elementary constitution by the vital influences of the juice. This is the first and greatest step in the process of assimilation. It is here that dead matter receives its first impressions from the properties vivification and vital affinity (§ 216, 218). The chemists tell us

that the process is a chemical one; and that, notwithstanding the various, and unique, and astonishing devices of nature for the elaboration of the gastric juice, they would persuade physiologists into the belief that many different processes of the laboratory will generate a gastric juice with all the unique properties that appertain to the fluid as elaborated from the blood by the various modifications of organization which were instituted by Almighty Power for these specific objects. And having been thus regardless of the most sublime and profound institutions of that Power, they proceed to assume that the product of these artificial compounds, in their action upon food, is the homogeneous chyme of living nature, and which is apparently the same in all animals, whatever the kind or the variety of food. But the chemist is met at the very threshold by the fact, that there is nothing in organic nature itself that can elaborate that fluid from the blood but that particular part of the great system of mucous membranes which forms a component part of the stomach (§ 135, a).—Notes N R.

308. The foregoing relates to complex animals; but analogy, as well as observation, renders it evident that the inferior races possess an or-

ganization which is equivalent to the stomach (§ 251).

309. In most animals that consume food of a solid nature, there are preparatory organs which assist mechanically, by dividing the food. The construction of these organs of mastication, both as to their osseous and muscular parts, has a strict reference to the kind of food upon which the animal is destined to subsist. Animals of prey are furnished with organs for the destruction of life and organization; since no substance which possesses life can undergo digestion, and all solids must be divided to admit of a free access of the gastric juice and saliva.

310. The organs of mastication are more various than any other parts; yet so uniform in each species, so allied among numerous species, that naturalists have taken these characters not only as significant of the species, but as the foundation of a systematic distribution

of the species into genera, and of genera into orders.

311. Where the usual organs of mastication are deficient in animals, the species is often supplied with means in the stomach itself for reducing the aliment to a soft substance, so that it may be penetrated by the gastric juice. The stomach of the armadillo, which subsists on insects, and of the granivorous birds, is endowed with a powerful muscle for crushing, or grinding the food. The stomachs of other animals are armed with bony or horny parts, as in many insects

312. The food is moved about in the stomach by the muscular action of the organ; but so peculiar and exquisite is the modification of irritability of the pyloric orifice, the food is not permitted to pass this outlet till it is converted into chyme (§ 278). Much of the aqueous portion, however, is early and rapidly absorbed by the stomach.

313. When, however, as we have seen, the irritability of the pylorus is artificially modified, as in disease, it will often allow undigested food to pass, more or less readily, into the duodenum (§ 278). But it is more remarkable that it will suffer many hard, indigestible substances to escape, while it detains such as are most congenial to its nature. The passage of indigestible substances is effected gradually by repeatedly presenting themselves at the pylorus, and thus so habituating the irritability of that orifice to their own irritant effects, but not to those of digestible food, that they are allowed to pass, while

the latter is detained; the stomach thus electing what is most congenial to its nature and to the wants of life (§ 188, &c., 539 a, 543, 551).

314. The saliva, bile, and pancreatic juice are auxiliary to the gastric juice, though how far is considered problematical. The liver is found, under a great variety of forms, in all animals whose structure can be made the subject of ocular demonstration, and it is known to generate bile in all instances. The pancreas and salivary glands occur in all the mammifera, birds, and reptiles, and in many fishes, mollusca, and insects.

From the general occurrence, therefore, of the foregoing organs, it cannot be doubted, independently of the more direct facts, that the fluids which they secrete have an important vital agency in the pro-

cess of assimilation.

315. Animals which live on vegetables have larger salivary glands than such as feed on animal substances; and, since vegetables require greater assimilating means than animal food, it is a just inference from final causes that the saliva answers a far more important object than, as is commonly imputed to it, of moistening the food and facilitating its passage to the stomach. On the other hand, however, it has been with still less reason imagined by others that it contributes more than the gastric juice to the conversion of food into chyme. But here, as on all speculative questions, some distinguished chemists refer the agency of the saliva in the process of digestion to the atmospheric air it conveys to the stomach, while others of equal renown attribute this high office to its own specific virtues.

316. The bile and pancreatic juice mingle with the chyme in the upper part of the duodenum, where it is probable that the latter fluid contributes an assimilating influence analogous to that of the saliva; while the disappearance of some of the components of the bile, and other relative facts, show a direct connection of this fluid with the process of assimilation. The bile also separates the excrementitious from the nutritious part of the chyme; the former portion occupying

the centre of the canal, and the latter the parietes (417, b).

Connected with these important uses of the bile is its well-known function of maintaining peristaltic action. Such, therefore, being its great final causes, we may safely reject the hypothesis of the mechanical theorists, that the liver, like the lungs, is designed to depurate the blood. The injury consequent on the failure of the liver, by experiment or otherwise, to perform its function, no more proves its supposed depurating office than a like contingency befalling the stomach would place that organ in the same category.—See § 1031–1033.

317. The intestinal tube, like the roots of plants, is supplied with absorbing vessels, which are called *lacteals* in animals of complex organization. The nutritive part of the chyme is taken up by these vessels, where it undergoes a farther assimilation, and receives the

name of chyle.

Nothing is absorbed by the lacteals which is offensive to their exquisitely modified irritability, excepting under the circumstances

already set forth (§ 278).

318. In the higher animals the chyle is transmitted by the lacteals to the thoracic duct, and by this vessel to the left subclavian vein, where it mingles with the general mass of blood. Thence it passes to the right cavities of the heart to be sent to the lungs, where it re-

ceives another important impress of vivification, parts, for the first time, with a portion of its carbonaceous matter, and undergoes a development of its coloring principle. From the lungs, it passes with the old blood, with which it is now fully incorporated, to the left cavities of the heart, to be transmitted to all parts of the body to under-

go the last act of assimilation.

319. Assimilation advances progressively from the first conversion of food into chyme till the nutritive matter becomes vitally united with the solid parts. At each step of the process, in the stomach, in the duodenum, through the lacteals, in the lungs, and at its final destination, the degree and kind of assimilation is forever the same, at each of its stages, in every species of organic beings; thus denoting specific powers and laws by which all this unvarying exactness is maintained (§ 42).

Assimilation is more simple in animals low in the scale of organi

zation; but close analogies prevail throughout:

320. The chyle is found to exhibit globules under the microscope, of which some are reddish. It is said, also, that they have been seen in the chyme; but Müller thinks that impossible, as the lacteals, according to him, have no open orifices, and, therefore, the globules could not be admitted through the "invisible pores" of the closed lacteals. These vessels, however, have open terminations by the villi of the intestines (§ 275, 1089).

These questions as to the existence and shape of the globules of blood, chyle, milk, &c., are of very little practical importance and are apt to lead to much waste of time, and encumber medicine with speculation and false doctrine; while the instrument, through the aid of which the imagination is thus sent upon its airy flight, is also the imbodyment of a thousand falsehoods in the path of truth (§ 131, 251).

321. Since, however, no one doubts that the nutritive part of the chyme undergoes a very positive change in the lacteals (§ 320), and a higher degree of assimilation, the proof is the same here, as in absorption by plants, that the fluid is not taken up and carried forward by

capillary attraction (§ 289-291).

322. Looking back upon the variety of parts which are concerned in the work of assimilation; their exact adaptation to each other; their peculiarities in different species of animals according to the nature of their food—varying, indeed, more or less in every species, yet always alike in all individuals of the same species; the prevalence of four specific digestive fluids, and each of these analogous in all animals, notwithstanding the variety in the structure of the secreting organs, yet only generated, respectively, by one special part, their production in unusual quantities, especially of the gastric juice, to meet the exigencies of digestion; the apparently exact similarity in the composition of the chyme of all animals, whatever the nature and the variety of the food; it appears to be one of the highest absurdities to suppose that all this complexity of parts, all this magnificence and variety in Design, should be merely intended to subserve a chemical reduction of food in the stomach, especially, too, as all that is known of chemistry is in conflict with every part of this stupendous whole. And when we pursue the other steps through which the great end of digestion is attained, and steadily regard each individual part forever giving rise to certain unvarying results, each part in its anatomical

and vital relations to all the rest, the necessity of every part to every step in the process of assimilation, the necessity of the whole to every secreted solid and fluid, the derivation of the whole unique and forever exact variety (millions upon millions, § 41-46) from four elements mainly, out of a homogeneous fluid which embraces yet fourteen other elements, the necessary co-operation of many of the secreted fluids toward their own formation individually, and toward every formation in the complex animal—when, I say, we duly consider this labyrinth of complexities, moving on in one unvarying round of harmonious action and results, moved by a power within which has no known analogy in the world where chemical results obtain, we may reconcile unbelief in all this Design with a yet higher order of infidelity, but certainly not with the ordinary promptings of reason, or with the plainest rules of evidence (§ 638).

But, let us analyze, in another section, the great plan of nature for

the maintenance of organic life in animals.

323. Let us analyze, after the manner of Cuvier, the constitution of animals in respect to the subserviency of the various parts of the fabric to the single function of digestion, and according to the nature of each species of animal; and when we shall have reflected upon the principles which determine the coincidences, and see that no one of them can be explained by any of the forces and laws of the inorganic world, let us cast from us, as unworthy a thoughtful mind, the supposition that the final act, or that of digestion, is a chemical process; and let us also apply the same induction to every other process

of living beings.

"Every organized being," says Cuvier, "forms a whole, a unique, and perfect system, the parts of which mutually correspond, and con cur in the same definite action by a reciprocal reaction. None of those parts can change without the whole changing; and, consequent ly, each of them, separately considered, points out and marks all the others. Thus, if the intestines of an animal are so organized as only to digest flesh, and that fresh, it follows that the jaws of the animal must be constructed to devour prey, its claws to seize and tear it, its teeth to eat and divide it, the whole structure of the organs of motion such as to pursue and catch it, its perceptive organs to discern it at a distance. Nature must have even placed in its brain the necessary instinct to know how to conceal itself and lay snares for its victims. That the jaw may be enabled to seize, it must have a certain-shaped prominence for the articulation, a certain relation between the position of the resisting power and that of the strength employed with the fulcrum; a certain volume in the temporal muscle, requiring an equivalent extent in the hollow which receives it, and a certain convexity of the zygomatic arch under which it passes. This zygomatic arch must also possess a certain strength to give strength to the masseter muscle. That an animal may carry off its prey, a certain strength is requisite in the muscles which raise the head; whence results a determinate formation in the vertebræ and muscles attached, and in the occiput where the muscles are inserted. That the teeth may cut the flesh, they must be sharp, and they must be so more or less according as they will have more or less exclusively flesh to cut. Their roots should be more or less solid, as they have more and larger bones to preak. All these circumstances will, in like manner, influence the development of all those parts which serve to move the jaw. That the claws may seize the prey, they must have a certain mobility in the talons, a certain strength in the nails; whence will result determinate formations in all the claws, and the necessary distribution of muscles and tendons. It will be necessary that the forearm have a certain facility in turning, whence, again, will result certain determinate formations of the bones which compose it. But, the bone of the forearm, articulating in the shoulder-joint, cannot change its structure

without this also changes."

Again, observe what may be inferred from some other given part. as from the shape of the bones: "The formation of the teeth bespeaks that of the jaw; that of the scapula that of the claws; just as the equation of a curve involves all its properties. So the claw, the scapula, the articulation of the jaw, the thigh-bone, and all the other bones separately considered, require the certain tooth, or the tooth requires them, reciprocally; and, taking any one of them, isolated from the skeleton of an unknown animal, he who possesses a knowledge of the laws of organic economy, could expound every other part of the animal. Take the hoof, for example. We see, very plainly, that hoofed animals must all be herbivorous, since they have no means of seizing upon prey. We see, also, that having no other use for their forefeet than to support their bodies, they have no occasion for a powerfully-framed shoulder; whence we infer, what is the case, the absence of the clavicle and acromion, and the straightness of the scapula. Not having any occasion to turn their fore-legs, their radius will be solidly united to the ulna, or, at least, articulated by a hinge-joint, and not by ball and socket, with the humerus. Their herbivorous diet will require teeth with a broad surface to crush seeds and herbs. This breadth must be irregular, and for this reason the enamel parts must alternate with the osseous parts. This sort of surface compelling horizontal motion for grinding the food to pieces, the articulation of the jaw cannot form a hinge so close as in carnivorous animals. It must be flattened, and correspond with the facing of the temporal bones. The temporal cavity, which will only contain a very small muscle, will be small and shallow," &c. (§ 169, f).

324. An intestine, claw, tooth, hoof, or other bone, therefore, of an unknown animal being given, we may construct a skeleton that shall be nearly true to nature in all its parts. We may then proceed to cover it with muscles; and, lastly, we can tell from that tusk, or claw, or hoof, or other bone, what was the structure of the digestive apparatus, and to what kind of food the gastric juice was specifically adapted, and what were the peculiar instinct and habits of the animal,—so special is the adaptation of all other parts of the organization, both in animal and organic life, and all the habits and instincts of animals, to the peculiarities of the digestive organs in every species (§ 18).

325. Now the whole of the foregoing mutual concurrence of all parts of the body, the adaptation of each part to the others in structure and use, being directly designed to subserve the purposes of digestion, and since it cannot be seriously entertained that any physical or chemical force is concerned in such a labyrinth of harmonious structure and actions, and so distinguished throughout by a multitude of the most consummate Designs, and all conspiring to one common end, it is manifestly absurd to imagine that digestion, the final cause of the

whole is carried on by agencies which have no connection with the various subordinate means (§ 14, 74, 80, 117, 129 i, 133–137, 143, 155, 156, 169 f, 266, 303 $\frac{1}{4}$ a, 306, 318, 336, 387, 399, 422, 514 h, 524 d, 525, 526 d, 528 c, 638, 649 d, 733 b, 764 b, 811, 847 c, 848, 902 f, 905).

326. What we have now seen of fundamental Design in the construction and subservience of all parts to the function of assimilation, and of the exact concurrence of the whole toward the incipient step, may well prepare the mind to realize the same Design throughout the whole system of organic processes, the same exact foundation in anatomical structure, and in vital properties, the same precise and everlasting laws (\S 169, f). Do we look again, therefore, at the stupendous fabric upon which, and its special vital endowments, the laws of sympathy depend? Astonishment abates, and unbelief yields as well to the force of analogy as to direct demonstration.

327. The philosophy of assimilation applied pathologically, and in conformity with the doctrines of solidism, is the following: The function of assimilation, being performed by the organic properties through their media of action, there will be a corresponding change in the elementary combination of the new compounds which are added to the parts affected, and the same morbid condition of the vital proper-

ties will be imparted to the new compounds.

328. If the stomach be diseased, then the nature of the gastric juice will be altered according to the manner in which the properties of the stomach may be affected. If, also, we allow, in this case, that the chyme will have a corresponding variation, and that this will in itself affect the whole character of the circulating mass of blood, so that the new elementary combinations, those of the solids and secreted fluids, will be more or less modified in all parts, we shall in no respect compromit the consistency of nature, or the fundamental principles of physiology (§ 44, 52, 78, 153-155, 218-220). However such admission may look like humoralism, it has no affinity with it. The whole process resolves itself into a primary disease of the solids; and the modified condition of the blood, which I am now supposing, does not derange the vital properties and actions of the system (§ 156 b, 845, &c.). But when chylification is affected by diseased states of the stomach, reflex nervous actions are then so exerted by that organ upon other parts, that their vital states do actually sustain a change, and often a far greater one, from that sympathetic cause. This more general modified condition of the solids contributes still farther to modify the new combinations, and to give rise to what are called vitiated secretions. The most striking examples are seen, of course, when digestion fails altogether, and the solids become universally affected by disease, as in fever (§ 143 c, 148, 657 b, 776, &c.).

329. If the heart and vascular system at large feel, mainly, the influence of gastric or some other local disease, the blood is always more or less affected in its composition, and assimilation is otherwise variously modified in all other parts, not only in consequence of the change in the blood, but of the affection of all the organs and fluids which are concerned in assimilation. Nothing affects the composition of the blood so rapidly as disturbances of the vital conditions of the heart and blood-vessels; or, perhaps, I should rather say of the extreme capillary blood-vessels. Nothing can prove more distinctly the truth of solidism and the fallacies of humoralism; especially those

more instantaneous changes which are effected in the entire circulating mass of blood by abstracting only an ounce of it from the arm (§ 845, &c., 952).

330. Now, suppose, instead of treating disease upon some broad principles, we were to undertake the specific object of the humoralists in any of the foregoing cases (§ 327-329); that is to say, the restoration of the blood in its composition and nature. The humoral pathologist would attempt its direct medication, in the vain hope that his drugs can produce, by their direct action upon the fluid, that natural combination of its elements, and that natural state of its vital properties, for doing which Nature has provided the whole system of the great vital organs, and many living secretions (§ 845, &c.). Since, therefore, the humoralist has not a physiological principle for his government, he has departed wholly from nature. The duty of cure thus devolves upon the solidist, who proceeds to restore assimilation by reestablishing the natural condition of the various tissues and organs whose functions had become deranged and had been the cause of the altered condition of the blood; and this is effected according to the manner set forth in my chapter on the modus operandi of remedial agents. There, too, you shall find, as well as in my disquisitions upon the philosophy of solidism, that the living solids are the only agents which can possibly effect any salutary changes in the pabulum vita, and, therefore, that when the former are diseased along with the latter, they must take the initiating step both in the morbid and healthy processes. Just in proportion, therefore, as the solidist improves the condition of the diseased organs, assimilation will approximate its natural state, and the blood be regenerated according to established physiological laws.—Note R p. 1123.

331. The condition, therefore, of the blood and of the products elaborated from it, in all cases of disease, should be regarded only as more or less significant of the morbid changes which may affect the

solid parts.

332. Having now gone over the general philosophy relative to assimilation, I shall proceed to consider its principal element, or what is denominated

THE PHYSIOLOGY OF DIGESTION.

In my investigation of this subject I shall enter rather extensively upon the ground of Organic Chemistry, in all its applications to the science of medicine; since it is here, especially, as said in the Commentaries, that chemistry has reared its batteries, and from whence it sends forth its artillery into the various dominions of organic life. A contrast will be instituted under the general designations of Physiology and Organic Chemistry, in their relation to healthy and morbid processes.

333. The doctrines of life, as hitherto expounded, should be applicable to all the problems in organic beings which may seem to a superficial observer to fall under the laws of chemistry, or of physics. Such problems are especially presented by digestion, respiration, and the production of organic heat; and these are the main intrenchments of chemistry. If the philosophy, therefore, which I have thus far propounded lie at the foundation of the foregoing results, it is probable that chemistry must be abortive in facts, and wild in conclusions; and

the more so as it advances to the greater obscurities in physiology pathology, and therapeutics. Such are the realities; and their exposure is the overthrow and the perpetual doom of organic chemistry.

334. Human physiology has been greatly vitiated, in recent times, by experiments upon animals, and conducted under the most unnatural circumstances. They have been extensively made, in a physiological aspect, without any view to the differences in organization and vital constitution between animals and man, and often with a reference to more functions than belong to any organic being. When prompted by pathological and therapeutical considerations the experiments have been liable not only to the foregoing objections, but to the greater one of assuming that there is no difference in the susceptibility of organs to the action of natural, morbific, and remedial agents in the varying states of health and disease (§ 149, 150, 240). These experimental fallacies, and the vast errors to which they have led and are still leading, I have considered extensively in my Essay on the Humoral Pathology.—See p. 839, § 1058 b, note.

In a physiological sense, the greatest evil attending the foregoing experiments consists in neglecting the fact that the constitution of man is different from that of animals when applying the results of such otherwise unnatural experiments to explain the vital laws which gov-

ern the functions of the human species.

The disparity increases between the natural laws and results of the human and those of vegetable organization, and others, again, of chemical affinities, just in the ratio of the difference between the varieties of organization and vital constitution, and the attributes of the

inorganic kingdom.

335. What, then, shall be said of those experiments which are conducted in the laboratory of the chemist to determine the physiology of the highest function of life, but in which organization takes no part, and the whole process is carried on by artificial "mixtures" and chemical reagents? This is now the almost universal philosophy, and therefore demands an investigation which shall lead either to its con-

firmation or to its overthrow (Rights of Authors, p. 912).

336. It is in the stomach that vitality is exemplified in its most impressive and astonishing aspects, and where unequivocal demonstrations abound that fluids, as well as solids, are endowed with the principle of vital operations, "a principle distinct from all other powers of nature" (§ 64, 339). It is here, especially, that nature has illustrated her distinction between the animate and inanimate world, and established her chain of connection. It is here, in the incipient change of dead into living matter, that we witness a full display of those powers which operate in the most elaborate organization, and an equal exclusion of the forces which appertain to dead matter. It is here the line of separation begins abruptly; but where analogies are presented in the conversion of dead into living matter, through new modes of combining the same elements; and admiration increases. as we mount along the entire function of assimilation, and find, at each tep of the ascending series, that the whole agency is committed to forces that have no existence in the inorganic world; that the whole is the harmonious result of a principle which may form an intermediate link between spirit and matter; and that there is no power within our control by which we can determine the nature of the changes.

Casting a glance at the vegetable world, we find the connection continued, by other analogous links, with elementary matter itself; but here, as in the higher department of nature, the line of separation is equally defined, however low in the scale of analogy may be the properties of life which have their beginning in vegetable organization.

It is here, then, at the threshold of life, as in the propagation of the species, that we especially witness a substitution for Creative Power; and, as all that appertains exclusively to the organic world was perfectly distinct in its Creation from the inorganic, so are the substituted processes of generation, and of the conversion of dead into living matter, equally distinct from the causes and results of inorganic processes

(§ 32, &c., 63, &c.).

For conducting that connected series of changes which make up the process of assimilation in animals, a complex apparatus has been provided, whose beginning in the vegetable kingdom, and whose progressive development in the higher kingdom, have been contrived upon consummate principles of Design, that the elements of matter shall be gradually brought into those perfectly new conditions, both as to composition and properties, which contradistinguish the organic from the inorganic kingdom, and thus as in all things else in the natural world, that abrupt transmutation of inorganic into organic matter which distinguished the Creative Act shall be avoided, and remain a characteristic of Creative Power (§ 14, 172, 325).

337. In the early part of this work, I set forth some general facts which evince an incongruity of doctrines that clearly divides the physiological world into three schools; one of them (pure chemistry) making no distinction between the properties and laws of organic and inorganic beings; a second (pure vitalism) contradistinguishing the two kingdoms in those fundamental conditions; and the third (chemicovitalism) blending the doctrines of chemistry and vitalism (§ $4\frac{1}{2}$, 820 c). Each of these denominations has interpreted the philosophy of digestion according to the general doctrines of life which are peculiar

to each.

338. Beginning with pure chemistry, we find the great leader setting forth the process of digestion in the following language in his late work on Animal Chemistry applied to Pathology and Therapeutics.

"Chymification," he says, "is independent of the vital force. It takes place in virtue of a purely chemical action,—exactly similar to those processes of decomposition and transformation which are known as putrefaction, fermentation, or decay" (§ 365).

It will be also seen from the foregoing quotation, that the chemist s regardless of his own rules of philosophy, and of the fundamental principles of chemistry; since he identifies the organizing act, or that which combines the elements of matter into complex organic compounds, with the chemical process that resolves these compounds into their ultimate elements. We are told, indeed, that this is "experimental philosophy," and that, therefore, we must submit to it (§ 350).

339, a. I shall now set forth the exact doctrine of the vitalists relative to the physiology of digestion, in the language of the same distinguished "reformer" whom I have quoted in the preceding section. It is true, the doctrines are as fundamentally opposed as contradiction can possibly make them. But, as will have been abundantly seen, the most remarkable characteristic of the writings of this distinguished

man are their palpable contradictions. Nor can there be any proof so conclusive of the radical distinction between the philosophy of life and the philosophy of chemistry, about which "the reformer" was

simultaneously concerned.

But, I will go back for a conflicting doctrine to the treatise "on Organic Chemistry applied to Physiology," published a year or two antecedently to his work "on Animal Chemistry;" by which we shall learn the extent of the confusion which pervades his writings, and the tardiness with which it is discerned by his medical disciples. In that

work he says,

"The equilibrium in the chemical attractions of the constituents of food is disturbed by the vital principle. The union of its ele-MENTS, so as to produce NEW COMBINATIONS AND FORMS, indicates the presence of a PECULIAR MODE OF ATTRACTION, and the existence of A POWER DISTINCT FROM ALL OTHER POWERS OF NATURE, namely, THE VITAL PRINCIPLE." "If the food possessed life, not merely the chemical forces, but This VITALITY would offer resistance to the vital force of the organism it nourished."-LIEBIG.

Such, then, is exactly the doctrine of the vitalist and solidist, mistaken by the chemist for his own, when he happened to be reasoning according to the promptings of organic nature. The same views are presented in the work on *Animal Chemistry* (§ 350).

339, b. And here, perhaps, it may be worth our while to say that the resuscitated chemical doctrine (§ 338) is apparently too wide a departure from fact even for that part of the British medical profession who have received most of the sayings of Liebig as oracular revelations; for we read in the late edition of the "Pharmacologia," now

devoted to the authorized philosophy (§ 349 d, 676 b), that,

"According to the experiments of Spallanzani, and still more recently of Dr. Beaumont, if, after putrefaction has actually advanced, a substance in such a condition be introduced into the living stomach, the process is immediately checked, and no signs of putrefaction are presented by the digested food, although were the same substances left at the temperature of 99° F., they would soon evince evidence of its progress. It is therefore clear that the VITAL POWERS of the digestive organs must, in such cases, reverse or suspend the ordinary chemical affinities" (§ 676, b).—Paris's Pharmacologia, p. 148. London, 1843. And such, in reality, is one of Liebig's conflicting statements.

And why should not the "vital powers reverse or suspend the ordinary chemical affinities" in all other cases of food, where it is far more obvious that such resistance does happen; and why may we not conclude that the law in relation to digestion has a wide foundation in living beings? Why does not the blood putrefy? Why not any other animal or vegetable fluid? Why not any living animal or vegetable

340. Let us now hear the student of organic nature upon the physiology of digestion. What says John Hunter, of whom it is said by one, that "he stands alone in our profession;" that, "in his immense career, every thing bore reference to one great idea, -the discovery and elucidation of nature's laws;" "who," says another, "was neither anatomist, physiologist, surgeon, nor naturalist, alone, but the most rema kable combination of all these which the world has yet seen;" for, "where," says another, "in the calendar of time, shall we look for an equal in the compass, the variety, and the depth of his researches into the mysteries of animal life, or for consequences such as those that have resulted from his labors to universal pathology;" while another apostrophizes, "how humble do any of the men of the present day appear when placed by the side of Hunter!" "The genius of Hunter," says another, "long ago explained the objections to other theories of digestion. These have been turned into ridicule to smooth the way for hypotheses that have no better foundation."

Well may we ask, what says John Hunter on the physiology of di

gestion?

"Digestion," he says, "is an assimilating process. It is a species of generation; but the curious circumstance is its converting both vegetable and animal matter into the same kind of substance or compound, which no chemical process can effect. Those who took it up chemically, being ignorant of the principles of the animal economy, have erroneously referred the operations of the animal machine to the laws of chemistry."

341. The illustrious George Fordyce, after a thorough experiment

al investigation of the subject, comes to the conclusion that,

"The changes which take place in the substances capable of giving nourishment, and, therefore, of being converted into the essential parts of the chyle, are TOTALLY DIFFERENT from those changes which take place any where but in the stomach, duodenum, and jejunum, when alive. Therefore, no experiment made any where, EXCEPTING IN THESE INTESTINES OF THE LIVING ANIMAL, can in the smallest degree influence the doctrine of digestion." "Food placed in all the chemical circumstances that can be conceived similar to those in which it is placed in the living animal, will never be converted into chyme, but will undergo other changes totally different." He finally adds, as the result of his own experiments out of the stomach, that, "whether we employ the gastric juice, or bile, or saliva, in no case has CHYLE, OR ANY THING LIKE IT, EVER BEEN PRODUCED." The reason is, that the gastric juice, like the blood, loses its vitality as soon as abstracted from the stomach. Hunter arrived at exactly the same conclusion from his observations (§ 364).

342. It is the opinion of Tiedemann, another distinguished inquirer

into the nature of digestion (§ 340, 341), that,

"All the phenomena of digestion and assimilation, and which are only observed in living bodies, appear to rest, as to their foundation, on the VITAL PROPERTY which organized liquids possess of producing, under certain circumstances, in other organic matters, similar changes that cause these bodies to acquire the properties themselves are endowed withal." Again:

"It cannot be mistaken that digestion is an operation exclusively the property of living bodies, and is in no way to be compared with the changes of composition which general physical forces and the play of chemical are capable of producing in inorganic matters. It must be

considered as a vital act, as an effect of life."

As to assimilation by vegetables, Tiedemann holds the same doctrine as Hunter, Fordyce, and all other physiologists whose opinions have survived the day on which they were promulgated. Thus:

"On the subject of the material changes which vegetable parts un-

dergo in nutrition, chemistry has hitherto given us no satisfactory information, simply because, being effects of life, such changes are beyond the domain of chemical science. All that we are authorized to admit is, that the changes of composition that occur during the nutrition of vegetables are the consequence of vital manifestations of activity, and not the effects of chemical affinities, such as are observed in inorganic bodies."

"All the attempts," he goes on, "of the iatro-mechanicians and iatro-chemists to reach this point (assimilation) have failed; and it is well ascertained that such ideas are both unsatisfactory and erroneous. We are therefore under the necessity of regarding them as effects, sui generis, as vital manifestations, founded on a power peculiar to, and inherent in, organic bodies."—Tiedemann's Physiology.

343. Turning to the greatest of French physiologists, we hear from him the same general protest against the corruption of medicine by

ingrafting upon it the physical sciences (§ $5\frac{1}{2}$, b).

344. In considering farther the physiology of digestion, I shall introduce, in the first place, a series of general conclusions which have been derived from chemistry, both as to digestion and other organic processes, and when in this respect and otherwise prepared, I shall state the remaining grounds upon which I rely more specifically for establishing the vital doctrine.

345. Let us hear, then, the distinguished chemist, Dr. Prout, as the

representative of those who mingle chemistry with vitalism.

"First," says Dr. Prout, "the stomach has the power of dissolving alimentary substances, or, at least, of bringing them to a semi-fluid

state. This operation seems to be altogether chemical.

"2d. The stomach has, within certain limits, the power of changing into one another the simple alimentary principles," and "this part of the operation of the stomach appears, like the reducing process, to be chemical; but not so easy of accomplishment. It may be termed the converting operation of the stomach.

"3d. The stomach must have, within certain limits, the power of organizing and vitalizing the different alimentary substances." "It is impossible to imagine that this organizing agency of the stomach can be chemical. Its agency is vital, and its nature completely unknown."

346. Such, then, is the doctrine of digestion as entertained by the chemico-vitalist (§ 345). But, from what we shall have seen of the absolute contradictions which abound in the writings of those who attempt the application of pure chemistry to the functions and results of organic life, we may expect that the chemico-vitalist will be equally inconsistent when he applies himself, at one time, to the phenomena of living beings, and, at another, reasons from the results of the laboratory to those phenomena. Accordingly, we find within a few pages of the foregoing doctrine of the chemico-physiologist, that he broadly affirms that

"There is no relation whatever between the mechanical arrangements and the chemical properties to which they administer," "There is no reason why the chemical changes of organization should result from the mechanical arrangements by which they are accomplished; neither is there the slightest reason, why the mechanical arrangements in the formation of organized beings should lead to the chemical changes of which they are the instruments"!

Here, then, in a single sentence, are not only the strangest contradictions, but a full admission that there is not the "slightest reason" for the application of chemistry to any process, function, or result of

living beings.

347. Nor is that all. For the chemico-vitalist, the same eminent chemist whom I have just quoted, goes on to say, that "with the living, the animative properties of organic bodies, chemistry has not the smallest alliance, and probably will never, IN ANY DEGREE, elucidate those properties. The phenomena of life are not even REMOTELY ANALogous to any thing we know in chemistry as exhibited among inorganic agents." And, as if to complete the overthrow of the chemical part of the philosophy of digestion, the same reasoner observes that, "the MEANS by which the peculiarities of composition and structure are produced, which is so remarkable in all organic substances, like the RESULTS themselves, are QUITE PECULIAR, and bear little or no resemblance to any artificial process of chemistry;" that "those who have attempted to apply chemistry to physiology and pathology have split on a fatal rock by hastily assuming that what they found by experiment to be wanting, or otherwise changed, in the animal economy, was the cause of particular diseases, and that such diseases were to be cured by supplying, and adjusting artificially, the principle in error. But the scientific physician will soon discover that Nature will not allow him to officiate as her journeyman, even in the most trifling degree."—Dr. Prout's Bridgewater Treatise.

348. And, to the same effect may be quoted Dr. Carpenter, one of the foremost, as we have seen, in the school of pure chemistry (§ 64, g).

"The agency of VITALITY," says this reasoner, in his Comparative Physiology, where he generally ridicules the term and all that is relative to it, "the agency of VITALITY, as Dr. Prout justly remarks, does not change the properties of the elements, but simply combines the ELEMENTS in modes which we cannot imitate"!

So, also, Dr. Roget, alike distinguished in the school of chemicovitalism (§ 64, f): "VITAL chemistry," he says, " is too subtle a power for human science to detect, or for human art to imitate."

And thus the eminent Wagner, not less arrayed on the side of

chemistry:

"The existence of one or more powers, commonly called VITAL powers, is not, however, denied. The final cause of the secretion of the gastric juice lies in the nature of the animal organism, and is unknown to us."—Wagner's *Physiology*, *London*, 1842, p. 346. And yet this distinguished observer is one of the manufacturers of gastric juice.

349, a. Thus might I go on with one after another, till I should have exhausted the whole that have attempted to confound the science of life with the science of chemistry, and prove by their own statements that there is not the slightest intelligible connection between them. Indeed, I have already, in the Medical and Physiological Commentaries, pointed out this universal admission (§ 626 b).

The ground of chemistry being thus virtually abandoned to the vitalist, it would seem superfluous to pursue an adversary who is always upon the retreat. But, as he flies, he is forever shooting from behind, and his Parthian weapons fall thickly and heavily upon the vast multitude. He must therefore be subdued into a practical acqui-

escence with those consistent principles of nature which exact his con-

sent, but not his compliance.

349, b. Perhaps no author has supplied so many examples of contradictions in great fundamental principles, and in so small a compass, as he who has so lately taken captive the physiological world. In the Preface to the Essays "On the Philosophy of Vitality and the Modus Operandi of Remedial Agents" I had occasion to say of the article on "Poisons, Contagions, and Miasma," in Liebic's "Organic Chemistry applied to Agriculture and Physiology," that "it is certainly the most stupendous exhibition of perverted facts, of combinations of conflicting doctrines, and of the rudest system of pathology and therapeutics, that can be found in the records of dreamy speculation."

It was objected by the editor of the London Lancet, that I did not prove my allegations (§ $5\frac{1}{2}$, a). Nor was it in any respect the object of that work to do so. I was satisfied with calling attention to the facts, and with what I had already published in the Medical and Physiological Commentaries. Since that day, the work on "Animal Chemistry" has appeared; and it is now my purpose to sustain the allegations of the "Preface," and this more especially from the objections alleged by Liebig against physiologists (§ 350, mottoes, a, b, c, and d).

I say, therefore, that we meet on the same page a purely chemical and a purely vital philosophy of digestion; and equally so of other important organic processes. That each is laid down without qualification, and with the *dictum* of a master, who is conscious that the preponderance he gives to the purely chemical philosophy of life will establish his Empire in that philosophy with an age more prone than

ever to the doctrines of materialism.

349, c. Let us, therefore, not be deceived; for, however this very extraordinary and successful pretender in medicine may beguile us with words, and seem to persuade rather than to rule, let us remember that, at most, he does but invalidate his own edicts by countermands, and that in the end he tells us that these apparently adverse decrees are, in their absolute import, one and the same; that they are consistent laws delivered from the laboratory, though apparently in conflict on account of the opposing forces, the attraction and repulsion, which preside in the chemistry of nature; that, however, in reality, there is no difference whatever in the seemingly two great principles which lie at the foundation, which are one and identical, since "the mysterious vital principle can be replaced by the chemical forces;" and since, also, "the vital force unites in its manifestations all the peculiarities of the chemical forces, and of the no less wonderful cause which we regard as the ultimate origin of electrical phenomena." And again, "in the processes of nutrition and reproduction, the ultimate cause of the different conditions of the vital force are chemical forces" (§ 64, e). -LIEBIG'S Organic Chemistry; and Animal Chemistry.

349, d. It is painful to speak thus of one so highly endowed, so devoted in mind, so accomplished in chemistry; but science and humanity demand the sacrifice. But, again, I wish to be understood, that neither here, nor in any other case, is it the individual of whom I speak, but of his doctrines alone (§ 1 b, 4 b). Nor yet would the doctrines of an individual become the subject of extended remark, did they not represent the existing state of the three high branches of medicine. The gigantic physical school had too much of the Pro-

tean character, too little unity of purpose, and demanded greater sta-The learned men of a great Nation, The British Association for the Advancement of Science, united in the object, and bestowed the honor of achieving the enterprise upon a foreign Chemist. The note of proscription has been sounded in high quarters, in due conformity ($\S 5\frac{1}{2}$ a, $350\frac{3}{4}$ kk), and medical philosophy has nothing to hope even from a spirit of toleration. The subject, therefore, must be brought to the test of observation and reason, and he who arraigns the authorized doctrines will cheerfully abide an unsuccessful issue (§ 1 b, 676 b, 709, note). I shall therefore dwell upon the conclusions of those who have engendered the corruptions, and shall array them in all the force demanded by the magnitude of my subject, that we may the better realize the shallowness of that pretended philosophy which has so lately swept, like a hurricane, over the intellectual world, that we may see, in the system of contradictions, the equal fallacy of that school who endeavor, with great sincerity, to mingle the conflicting principles, and that we may the better cultivate and enjoy the simple and consistent philosophy which nature teaches. Nor will I yet leave this general reference to that stupendous system of assumption and contradiction which was so lately hailed by physiologists as the harbinger of a total revolution in medical science, ay, in the very practice of medicine, without showing you the depth of the materialism in which it was founded. I say nothing now of the avowed infidelity to which it has led. Examples of that disregard of instinctive faith I have already placed in their proper connection with my subject.* But, I will merely present, in relief, from Liebig's revolutionary work, a doctrine of the chemical school, from which, if I mistake not the ambition of intellectual and immortal beings, the very impulse of nature will turn the most indifferent with a loathing aversion. We shall see from it, also, how entirely degraded to the rank of the merest matter is every thing relating to organic life; even man Thus, then, "the Reformer," in behalf of the school of himself. chemistry:

349, e. "Physiology has sufficiently decisive grounds for the opinion that every motion, every manifestation of force, is the RESULT of a transformation of the structure or of its substance; that every conception, every mental affection, is followed by changes in the chemical nature of the secreted fluids; that every thought, every sensation, is accompanied by a change in the composition of the substance of the brain." "Every manifestation of force is the RESULT of a transformation of the structure or of its substance."—See p. 158, no. 5½.

And now may it not be reasonably asked, what is the cause of those chemical changes in the cerebral substance which give rise to "every conception, every mental affection, every thought, and every sensation" (§ 175 c, 500 n, 1054, 1076 a) those "manifestations of force"?

Many organic chemists, however, are disposed to admit a spiritual part, and they should therefore recollect that the existence of a principle of life is not less substantiated by facts than the existence of the soul, which they are so ready to concede when inviting our attention to the physical doctrines of life.

350. I have just said that I would present such an array of contra-

^{*} See Medical and Physiological Commentaries, vol. ii., p. 122-140. Also, the Essay on the Vital Powers, in vol. i. Also TACITUS' Dialogue Concerning Oratory.

dictory opinions on the physiology of digestion, and the general philosophy of life and disease, from the two brief National Essays by Liebig (§ 349, b), as should induce physiologists to retrace their steps, and thus make some atonement to the science which was surrendered with an acclamation that had been worthy the original institution of medicine.

In the first place, however, with a view to the cause which I advocate, and in justice, also, to able and independent philosophers, I shall quote the following remarks from a letter addressed to myself by a distinguished writer, of Manchester (England):

"Manchester, May 5, 1846.

"DEAR SIR.

"I made your pamphlet (a Lecture on Digestion) the subject of a Paper which I read before the MANCHESTER LITERARY AND PHILO-SOPHICAL Society, and which provoked a discussion two nights. result was almost unanimously in favor of your views in reference to the Philosophy of Digestion. I am, &c.,

"CHARLES CLAY, M.D."

I shall now exhibit, in parallel columns, the new philosophy which forms the present science of medicine, preceded by some appropriate mottoes.

a. "Animal and vegetable physiologists institute experiments without being acquainted with the circumstances necessary to the continuance of life—with the qualities and proper nourishment of the animal or plant on which they operate—or with the nature and chemical constitution of its organs. These experiments are considered by them as convincing proofs, while they are fitted only to awaken pity" (no. 50).

b. "All discoveries in physics and in Chemistry, all explanations of Chemists [!] must remain without fruit and useless, because even to the Great Leaders in Physicalogy, carbonic acid, ammonia, acids, and bases, are sounds without meaning, words without sense, terms of an unknown language, which awaken no thoughts, and no associations. They treat these sciences like the vulgar, who despise a foreign literature in exact proportion to their ignorance of it."—Liebic's Organic Chemistry applied to Physiology, &c. [See no. 2.]—(6) 1034).

c. "None of them (the most distinguished physiologists) had a clear conception of the

c. "None of them (the most distinguished physiologists) had a clear conception of the process of development and nutrition, or of the true cause of death. They professed to explain the most obscure psychological phenomena, and yet they were unable to say what fever is, and in what way quinine acts in curing it" (no. 2. 42). The off-reiterated conclusion follows, that IT IS RESERVED FOR CHEMISTRY TO RESOLVE THESE PROBLEMS.

d. "Thus medicine, after the fashion of the Aristotelian philosophy, has formed certain conceptions in regard to NUTRITION and SANGUIFICATION. Articles of diet have been divided into NUTRITIOUS and NON-NUTRITIOUS; but these THEORIES [1] being founded on observations DESTITUTE of the conditions most essential to the drawing of just conclusions, could not be received as expressions of the truth. How clear are now to us the relations of the different articles of food to the objects which they serve in the body, since organic chemistry has applied to the investigation her quantative method of research"! (§ 18, 409.)

e. "The limited acquaintance of physiologists with the methods of research employed in chemistry WILL CONTINUE TO BE the chief impediment to the progress of physiology, as well as a reproach which that science cannot escape."—LIEBIG'S Animal Chemistry.

f. "What has the sour, what have consciousness and intellect to do with the developf. "What has the soul, what have consciousness and intellect to do with the development of the human fœtus, or the fœtus in a fowl's egg? Not more, surely, than with the development of the seeds of a plant. Let us first endeavor to refer to their ultimate causes those phenomena of life which are not psychological; and let us beware of drawing conclusions before we have a ground-work. We know exactly the mechanism of the eye; but neither anatomy nor CHEMISTRY will ever explain how the rays of light act on conscious ness, so as to produce vision. Natural science has fixed limits which cannot be passed, and it must always be borne in mind that, with all our discoveries, we shall never know what light, electricity, and magnetism are in their essence, because, even of those things which are material, the human intellect has only conceptions. We can ascertain, however, the laws which regulate their motion and rest, because these are manifested in phe nomena. In like manner, the laws of vitality, and of all that disturbs, fro motes, or alters vitality, may certainly be discovered, although we shall never lears what life is" (§ 168). — Liebig's Animal Chemistry.

g. "For years past a tribunal has been established at Giessen, before which Liebig is at the same time accuser, witness, public prosecutor, advocate, and judge."—MÜLDER'S Reply to Liebig. Translation, London, 1846.
h. "Chemists and natural philosophers, accustomed to study the phenomena over which the physical forces preside, have carried their spirit of calculation into the theories of the

vital laws."-BICHAT's General Anatomy, vol. ii., p. 54.

- i. "Let a man be given up to the contemplation of one sort of knowledge, and that will become every thing. The mind will take such a tincture from a familiarity with that object, that every thing else, how remote soever, will be brought under the same view. A metaphysician will bring ploughing and gardening immediately to abstract notions; the history of nature will signify nothing to him. A chemist, on the contrary, shall reduce divinity to the maxims of his laboratory, explain morality by sal, sulphur, and mercury and allegorize the Scripture itself, and the sacred mysteries thereof, into the philosopher's extrap."

3501. To carry out the full object of the foregoing section, I shall devote another to a farther exhibition of the pathological and therapeutical doctrines which have been deduced by the author of the "new era in medicine" from his chemical and physiological elements, as their resulting compounds. This more extended display of theoretical and practical doctrines, as they came to us from the laboratory, will reflect a broad light upon the chemical hypotheses of digestion, nutrition, &c., as set forth in the preceding section, and show us, also, the extent of the probabilities which relate to the analysis of food and of the conclusions which are predicated of that analysis (§ 18, 409, 676 b), and, in brief, enable us to comprehend the nature and amount of the service which organic chemistry has rendered to the science of medicine (δ 5, 5 $\frac{1}{2}$ a, 376 $\frac{1}{2}$, 1029, 1030, 1034).

This otherwise isolated subject will be farther interesting, as I shall embrace in the quotations the whole science of medicine as founded on chemistry and physics, and thus place in contrast the systems of the two rival schools, and enable the reader to adjust their relative merits. To do this work of consigning chemistry to its legitimate pursuits the more effectually, I shall also expose, in an appropriate place, the chemical doctrine of animal heat in the language of him who is supposed to have settled the philosophy of that subject (§ 433-450, 676, 1043-1050).

And before proceeding to a farther exposition of the vital and chemical doctrines of digestion, I shall, in consideration of the general surrender of this subject to the laboratory of the chemist, exhibit the corroborating testimony of the distinguished Mülder that physiology and medicine have nothing to hope from observations conducted out of the living body (§ 350, nos. 48,49, also Lehmann, §1029, 1030).

By the method now contemplated obstacles may be removed, and the reader better disposed to consider maturely the grounds upon which I have placed the vital doctrine of digestion, and come the more willingly to the conclusion that none are so imperfectly qualified to interpret the properties and laws of organic beings as they who can reason alone from the slender and deceptive analogies supplied by inorganic nature, and artificial expedients.

It is certainly remarkable that this systematic exposure should be necessary at the middle of the nineteenth century, when arts and all other sciences, though more so the arts, are making a steady, sometimes an actorishing progress.

times an astonishing progress.

I may be mistaken in the importance which I have attributed to the innovations which have been made by organic chemistry upon medical philosophy. I know that I am but feebly sustained by others in my conclusions; though now and then a blaze of mind assures me that deep volcanic action is in smothered progress (§ 3763).

350½, a. We have, then, from the authorized works of Liebig (§ 349, d), in the first place, the following inductions, in the order of

their occurrence, of

Pathological Principles, or "Theory of Disease" (350, no. 59).

"Every substance or matter, every chemical or mechanical agency, which changes or disturbs the restoration of the equilibrium between the manifestations of the causes of waste and supply, in such a way as to add its action to the causes of waste, is called a cause of disease. Disease occurs when the sum of the vital force, which tends to neutralize all causes of disturbance, in other words, when the resistance offered by the vital force, is weaker than the acting cause of disturbance;"—with the reservation, nevertheless, that "the cause of disturbance, or chemical force and the vital force, are one and identical."

 $350\frac{1}{2}$, b. "Death is the condition in which all resistance on the part of the vital force entirely ceases. So long as this condition is not es-

tablished, the living tissues continue to offer resistance."

350½, c. "To the observer, the action of a cause of disease exhibits itself in the disturbance of the proportion between waste and supply which is proper to each period of life. In medicine, every abnormal condition of supply or of waste, in all parts, or in a single part of the body, is called *disease*."

350½, d. "It is evident that one and the same cause of disease will produce in the organism very different effects, according to the period

of life. A cause of disease which strengthens the causes of supply, either directly or indirectly, by weakening the action of the causes of waste, destroys, in the child and in the adult, the relative normal state of health; while in old age it merely brings the waste and supply into

equilibrium.

350½, e. "A child, lightly clothed, can bear cooling by a low external temperature without injury to health. [!] The force available for mechanical purposes and the temperature of its body increase with the change of matter which follows the cooling; while a high temperature, which impedes the change of matter, is followed by disease."

 $350\frac{1}{2}$, f. "A deficiency of resistance, in a living part, to the causes of waste, is, obviously, a deficiency of resistance to the action of the

oxygen of the atmosphere.

 $350\frac{1}{3}$, g. "When, from any cause whatever, this resistance diminishes in a living part, the change of matter increases in an equal de-

gree.

350½, h. "Now, since the phenomena of motion in the animal body are dependent on the change of matter, the increase of the change of matter in any part is followed by an increase of all motions. According to the conducting power of the nerves, the available force is carried away by the nerves of involuntary motion alone, or by all the nerves together. [!]

 $350\frac{1}{2}$, i. "Consequently, if, in consequence of a diseased transformation of living tissues, a greater amount of force be generated than is required for the production of the normal motions, it is seen in an acceleration of all or some of the involuntary motions, as well as in a higher temperature of the diseased part. This condition is called

fever.

 $350\frac{1}{2}$, j. "When a great excess of force is produced by change of matter, the force, since it can only be consumed by motion, extends itself to the apparatus of voluntary motion. This state is called a

febrile paroxysm.

 $350\frac{1}{2}$, k. "In consequence of the acceleration of the circulation in the state of fever, a greater amount of arterial blood, and, consequently, of oxygen, is conveyed to the diseased part, as well as to all other parts; and, if the active force in the healthy parts continue uniform, the whole action of the excess of oxygen must be exerted on the diseased part alone (§ 350, no. 10).

 $350\frac{1}{2}$, l. "According as a single organ, or a system of organs, is affected, the change of matter extends to one part alone, or to the whole

affected system.

350½, m. "Should there be formed, in the diseased parts, in consequence of the change of matter, from the elements of the blood or of the tissue, NEW PRODUCTS, which the neighboring parts cannot employ for their own vital functions; should the surrounding parts, moreover, be unable to convey these products to other parts, where they may undergo transformation, then these new products will suffer, at the place where they have been formed, a process of decomposition analogous to fermentation or putrefaction"!

350½, n. "If we consider the fatal accidents which so frequently occur in wine countries from the drinking of what is called feather white wine, we can no longer doubt that GASES OF EVERY KIND, whether soluble or insoluble in water, possess the property of permeating ans

mal tissues, as water penetrates unsized paper [!] (§ 350, no. 24). This poisonous wine is wine still in a state of fermentation, which is increased by the heat of the stomach. The carbonic acid which is disengaged penetrates through the parietes of the stomach, [!!] through the diaphragm, [!!!] and through all the intervening membranes, [!!!!] into the air-cells of the lungs, [!!!!!] out of which it displaces the atmospherical air. [!!!!!!] The patient dies with all the symptoms of asphyxia caused by an irrespirable gas, [!] and the surest proof of the presence of carbonic acid in the lungs is the fact, that the inhalation of ammonia, which combines with it, is recognized as the best antidote against this kind of poisoning"!—(§ 1055).

"No doubt a part of these gases may enter the venous circulation through the absorbent and lymphatic vessels, and thus reach the lungs, where they are exhaled; [!] but the presence of membranes offers not the slightest obstacle to their passing directly into the

cavity of the chest"! (§ 349 d, 447 b, 827 h).

350½, o. "It is known that in cases of wounds of the lungs a pecu liar condition is produced, in which, by the act of inspiration, not only oxygen but atmospherical air, with its whole amount of nitrogen, penetrates into the cells of the lungs. This air is carried by the circulation [!] to every part of the body, [!!] so that EVERY PART is inflated or puffed up with the air, as with water in dropsy. [!] This state ceases, without pain, as soon as the entrance of the air through the wound is stopped."

 $350\frac{1}{2}$, p. "The frightful effects of prussic acid, which, when in spired, puts a stop to all the phenomena of motion in a few seconds, are explained in a natural manner by the well-known action of this compound on those of iron, when alkalies are present"!! (§ 494 dd,

827 d, 904 b).—Liebig's Animal Chemistry.

350½, q. The foregoing doctrines, with the humoral philosophy as quoted in § 350, nos. 40-45, make up the whole science of pathology as delivered to us from the laboratory; and such, too, are the doctrines which are hailed as the foundation of "a new and the greatest era of medicine." There can be no doubt, however, that deliberate investigation will satisfy every mind that they are unintelligible, impracticable, absurd; and, consequently, that the whole pretended system of physiology from which they are deduced, is equally unworthy the dignity of reason.

 $350\frac{2}{3}$, a. I shall now employ the same authorized chemist (§ 349, d) to give the last blow to his baseless fabric, and to scatter its fragments beyond the reach of idolatry itself. This will be done by setting forth, in the language of the author, his deductions from the physic-

logical and pathological doctrines of the laboratory, as to

The Chemical Treatment of Disease (§ 350, no. 59).

"The accelerated change of matter, and the elevated temperature in diseased parts, show that the resistance offered by the vital force to the action of oxygen is feebler than in the healthy state. But this resistance only ceases entirely when death takes place (nos. 1, 46). By the artificial diminution of resistance in another part (as by blisters, sinapisms, or setons), the resistance in the diseased organ is not, indeed, directly strengthened; but the chemical action, the cause of the charge of matter, is diminished in the diseased part, being direct-

ed to another part, where the physician has succeeded in producing a still more feeble resistance to the change of matter, to the action of oxygen.

350\frac{3}{3}, b. "A complete cure of the original disease occurs, when external action and resistance, in the diseased part, are brought into equilibrium. Health, and the restoration of the diseased tissue to its original condition, follow, when we are able so far to weaken the disturbing action of oxygen, by any means, that it becomes inferior to the resistance offered by the vital force, which, although enfeebled, has never ceased to act; for this proportion between these causes of change is the uniform and necessary condition of increase of mass in the living organism."

350²/₃, c. "In cases of a different kind, where artificial external disturbance produces no effect, the physician adopts other indirect methods to exalt the resistance offered by the vital force. He diminishes, by blood-letting, the number of the carriers of oxygen (the globules), and, by this means, the conditions of change of matter; he excludes from the food all such matters as are capable of conversion into

blood, &c.

 $350\frac{2}{3}$, d. "If he succeed, by these means, in diminishing the action of oxygen in the blood on the diseased part, so far that the vital force of the latter, its resistance, in the smallest degree, overcomes the chemical action; and if he accomplish this without arresting the functions

of other organs, then restoration to health is certain. [!]

3502, e. "Practical medicine, in many diseases, makes use of cold in a highly rational manner, as a means of exalting and accelerating, in an unwonted degree, the CHANGES OF MATTER. This occurs especially in certain morbid conditions, in the substance of the centre of the apparatus of motion; when a glowing heat and a rapid current of blood toward the head point out an abnormal METAMORPHOSIS OF THE BRAIN [!] (350, motto i, nos. 3, 5). When this condition continues beyond a certain time, experience teaches that all motions in the body cease. [!] If the change of matter be chiefly confined to the brain, then the change of matter, the generation of force, diminishes in all other parts. [!] The metamorphosis which decides the issue of the disease is limited to a short period. We must not forget that the ice melts and absorbs heat from the diseased part; that if the ice be removed before the completion of the metamorphosis, the temperature again rises; that far more heat is removed from the head than if we were to surround the head with a bad conductor of heat. There has obviously been liberated, in an equal time, a far larger amount of heat than in the state of health. That is to say, such is the pathology of cerebral inflammation, such the remedy, and such its modus operandi.

3502, f. "The self-regulating steam-engines, in which, to produce a uniform motion, the human intellect has shown the most admirable acuteness and sagacity, furnish no unapt image of what occurs in the

animal body.

"Every one knows, that in the tube which conveys the steam to the cylinder where the piston-rod is to be raised, a stop-cock of peculiar construction is placed, through which all the steam must pass. By an arrangement connected with the regulating wheel, this stop-cock opens when the wheel moves slower, and closes more or less completely

when the wheel moves faster than is required for a uniform motion. When it opens, more steam is admitted (more force), and the motion of the machine is accelerated. When it shuts, the steam is more or less cut off, the force acting on the piston-rod diminishes, the tension of the steam increases, and this tension is accumulated for subsequent use. The tension of the vapor, or the force, so to speak, is PRO-DUCED BY CHANGE OF MATTER, by the combustion of coals in the fireplace. The force increases (the amount of steam generated and its tension increase) with the temperature in the fire-place, which depends on the supply of coals and of air (§ 433, &c.). There are in these engines other arrangements, all intended for regulation. When the tension of steam in the boiler rises beyond a certain point, the passages for admission of air close themselves; the combustion is retarded, the supply of force (steam) is diminished. When the engine goes slower, more steam is admitted to the cylinder, its tension diminishes, the air-passages are opened, and the cause of disengage-Another arrangement of heat, or production of force, increases. ment supplies the fire-place incessantly with coals in proportion as they are wanted.

"If we now lower the temperature at any part of the boiler, the tension within is diminished. This is immediately seen in the regulators of force, which act precisely as if we had removed from the boiler a certain quantity of steam, or force. The regulator and the air-passages open, and the machine supplies itself with more coals.

"The body, in regard to the production of heat and force, acts just like one of these machines. With the lowering of the external temperature, the respirations become deeper and more frequent; oxygen is supplied in greater quantity and of greater density, the change of matter is increased, and more food must be supplied, if the temperature of the body is to remain unchanged."—Liebic's Animal Chemistry.

Here ends the science of therapeutics, as founded upon the preceding doctrines in physiology and pathology; and as the whole system is comprehended within the limits of the last three pages, the reader will readily contrast its brevity with the labors of the past, and will not fail to discover in this time-saving, thought-saving attainment of medicine, as well as in the impenetrability of the system itself, and the unequaled confidence with which it is set forth, the main causes of its success.

I shall now proceed, as proposed in § 3501, to demonstrate by the farther showing of chemistry itself, that physiology and medicine

have little to hope from the laboratory of the chemist.

350\(\frac{3}{4}\), a. Of the school of pure chemistry, and of an authority approaching to Liebig, is the distinguished Professor Mülder; less inconsistent than Liebig, but compelled to admit the existence of peculiar forces in living beings, yet positively denying them. He advocates, after the manner of Prichard, Carpenter, Fletcher, &c., the existence of all the properties of living beings in the elements of matter, which conducts him, like others, to the belief in Equivocal Generation; adopts the Catalytic theory of Berzelius, in which he differs fundamentally from Liebig (\(\frac{5}{3}\) 409, j); reasons, after the usual manner of the physical philosophers of life, from the results of inorganic processes; and overlooks entirely, except by admission of their existence, all the unique phenomena of living beings, and, perhaps, more than

any author of merit, is guided in his conclusions as to the processes and results of organic beings by the fallacious analogies which are studiously sought in the inorganic world. The whole system of vital philosophy, as taught by this distinguished Professor of Chemistry, may be so briefly set forth in extracts from his work on "The Chemistry of Vegetable and Animal Physiology," and they convey so forcibly the conjectural nature and worthlessness of chemical physiology, that the solection will contribute its important part toward the final expulsion of chemistry from the rich and fascinating domain of organic nature. The quotations will be made in the order of their occurrence in the work; and we learn from the first the author's opinion of force, which corresponds with my own as employed in the Commentaries, and as defended in my Examination of Reviews. Thus:

 $350\frac{3}{4}$, b. "It is a matter of indifference whether we conceive that the forces slumber in two substances, and are brought into operation by contact; or that these forces were present in the two bodies in an active state, previous to the contact, but produced the phenomena of combination only during the contact. The mode of considering this point is almost a matter of indifference; but we must always bear in mind that it is a power, a force which is exerted by the one, and which

acts upon the other."—MÜLDER.

 $350\frac{3}{4}$, c. The next quotation is preliminary to the total denial of the Principle of Life, and of all the properties in living beings excepting such as are active or "slumbering" in the elements of matter. Here, too, appears the fallacy of analogies derived from the laboratory of

the chemist. Thus:

"Adhering to what we observe and know with certainty, we calculate that every elementary body is endowed with a great many specific properties, which, to a large extent, are dependent on the same principle that causes their combination, and thus on the proportion and character of the *chemical tendency*. If we adopt this idea, we have the advantage of seeing somewhat of VITALITY IN DEAD MATTER. [!] It is an idea derived from the endless series of phenomena which are observed in the laboratory, in daily occurrences, and in nature at large" (§ 175, d).—Mülder.—(§ 1034, Lehmann).

3503, d. After the usual disquisition upon the "catalytic action" of platinum and other inorganic substances, we come next to the same application of catalysis, in connection with the ordinary laws of chemical affinity, to the interpretation of organic processes and results, as I have examined in the "Commentaries" (vol. i., p. 55-78). It comprehends Mülder's whole theory of life, and is a good specimen of the

author's analogical reasoning. Thus:

"Platinum possesses chemical tendency in a high degree; but it is of such a kind, that it does not react upon the platinum. Hence it may be inferred, that we have good reason for distinguishing by a peculiar name such actions as proceed from certain substances without reacting upon themselves; and we have to acknowledge that to the introduction, by Berzelius, of the peculiar term catalysis, we are indebted for a more correct idea of the nature of ordinary chemical action.

"What is called the *nascent state* of substances is that condition of the *elements* in which they exhibit both *analytic* and *catalytic* phenomena; in which, being free and unconstrained, not rendered powerless either by being agglomerated into masses, or by combination into compounds, they show themselves in their proper chemical condition that is, an active one, in which they can operate upon others, excite a slumbering energy, and cause combinations and decompositions, in which they themselves may either participate or not. This nascent state is the real chemical state of bodies. In that state both the elements and compounds exhibit themselves in their true character. In the organic kingdom the greater number of substances are actually in that condition; and to this nascent state we ought to ascribe the numerous peculiar phenomena apparent in organic substances" (§ 409).—MÜLDER.—(§ 1034, LEHMANN).

MÜLDER.—(§ 1034, LEHMANN)... 350\(\frac{2}{3}, e. \) The next quotation sets forth the whole practical application of the foregoing doctrines, and is a fine example of the chemical reduction of organic nature to the condition of dead matter, and one of the best summary exhibitions of chemistry in all its pretended re-

lations to living beings. It begins with the caption

"Disturbance of Chemical Equilibrium."

"It is a property of the chemical forces, when active in any substance, to excite analogous forces in others. We notice this especially in organic nature, and it is nowhere more strikingly illustrated than in the NUTRITION of animals. Blood, a Homogeneous fluid, circulates through very different parts of the body (§ 42). In the muscles it sustains muscles, in the liver it supplies the component parts of the liver, and from it the gall is there secreted; in the kidneys it maintains their various parts, and secretes the urine, &c. None of these secretions appear in the blood with their peculiar qualities; of some of them not even a trace is found. But the four organic elements of the whole are to be found in protein and its combinations, in the coloring matter of the blood, &c. The elements of protein might, no doubt, be transposed in the liver, &c., by means of catalysis, and so the component parts of the liver and gall be produced from it. It would only be necessary, then, that the constituent parts of the liver should be put into contact with the component parts of the blood, and the forces of affinity resident in the substance of the liver would not require to influence those in the protein, or to produce any chemical alteration in its component parts.

"Other causes, however, ought undoubtedly to be considered. For instance, a change of its component parts takes place in the liver itself, and, from the first, chemical forces actively operate therein. For the continual change of its component parts is a chief characteristic of every living organic substance. These forces may disturb the chemical equilibrium of other substances, and cause the formation of new products. If the constituents of the blood—the combinations of protein, the coloring matter, &c.—enter the liver when it is in a state of action, and are there put in contact with the gall during its secretion, and with the substance of the liver itself, which is in a state of continual alteration, then the result will be, that this change of their component parts having taken place, the action will be transferred to the elements of the blood, and will maintain the secretion. If, on the other hand, the constituents of the blood are in a state of continual change, then the circle of action in which they are involved will ex-

tend to the mass of the liver; and so with every organ (§ 18).

"We have, however, no more knowledge of the manner in which this secretion originally commences—whether it proceeds from the blood or from the secreting organ, [!] or whether each of these contributes its part—than with the manner in which the first germ of the whole organ, the liver, is produced, or in which the germ of the animal is converted into an animal. But the continuance of the action—the duration of secretion—entirely corresponds with some other phenomena, which we may observe separately, and which therefore throw light upon these animal actions. This is the case especially with fermentation, from which Liebig has drawn many illustrations, for the purpose of clearly exhibiting his ideas; and with the same view we

shall also avail ourselves of this process.

"Yeast changes sugar into carbonic acid and alcohol, and is at the same time changed itself. The latter change causes the former, and is only transferred to the sugar. If we substitute blood for yeast, and the liver for sugar, we may form an idea, more or less distinct, of the secretion of the gall. [!] The component parts of the blood are continually undergoing change. This constant change of the component parts in organic bodies is a chief cause of the continuation of their existence. The liver without intermission assumes new parts and loses others. This process we call nutrition. At the same time that the parts of the blood in the substance of the liver are thus undergoing change, chemical forces are excited; these forces are transferred to the elements of the blood, and so are enabled to produce from them the gall. This takes place the more easily, as the blood itself is also in a state of continual alteration, and thus readily yields to the impulse which, in some way or other, is communicated to it. As the impulse varies, so does the effect. Hence that great diversity in the secretion of very dissimilar substances, which are in a state of alteration, from the same fluid-that is, the blood, which is itself at the same time in a state of decomposition."-MÜLDER.

350\(^3\), f. In our next quotation we have an assumption founded on a begging of the very question at issue; that is to say, whether there be or not a radical difference in the original constitution of organic and inorganic nature. The author having assumed that there is no difference, proceeds, by the force of surmised analogies drawn from the probable constitution of inorganic matter, to repeat the assumption already stated that there are no other properties in living beings

than such as exist in the elements of matter. Thus:

"The idea of communication of forces is unsound; it is only what is substantial that we can communicate. Forces may be excited, they cannot be communicated. Hence it results that every transformation in plants is effected by the molecular forces of carbon, hydrogen, oxygen, and nitrogen,—the elements of carbonic acid, water, and ammonia,—the forces being excited in these elements by the plants themselves." "Any one who imagines that there is any thing else in action than a molecular force, than a chemical force, sees more than extien than a molecular force, than a chemical force, sees more than extended in the elements vary with the influence which certain agents—temperature, moisture, light, &c.—exert. By the aid of crucibles and retorts, therefore, compounds can be formed which differ from those produced by the organs of plants; while, from carbonic acid and water, plants can produce cellulose and oxygen, a result which cannot yet be imitated by art." "To express our idea in a

few words:-The elements of the organic kingdom, carbon, hydro gen, oxygen, and nitrogen, are susceptible of endless modifications For that reason they can form, with minute changes, a great diversity of products (§ 41); and by the operation of the same primary forces, they stand toward each other in entirely different relations from those assumed by all the other elements; so that THEY CAN PRODUCE a reculiar series of bodies, which are called organic substances"! " Organic substances, whether called germs or food, possess properties of a PE-CULIAR KIND, EXISTING IN THE FOUR ELEMENTS of which they are all constituted" !- MÜLDER.

 $350\frac{3}{4}$, g. The difficulty, therefore, with the chemists appears to lie in their habits of reasoning exclusively from what they observe of inorganic compounds and their elements, and an indisposition to admit that the Almighty superadded to organic beings a principle of life, while they allow the special creation of mind in animals. Nor does their philosophy permit them to imagine that the former may be as capable of governing all the processes of organic, as the latter is of animal life, and that the principle of life may be supposed, with as much reason as the principle of intelligence, to be imparted by the exact organization perpetuated from the Almighty Hand to new ac cessions to that organization; while the phenomena of life are far more multifarious and conclusive of the existence of a special principle than such as oblige the chemist to yield his assent to a mental principle distinct from the matter with which it is associated. Why, then, does not the chemist equally maintain the existence of mind, as of the properties of life, in the elements of matter, and that its development is alike owing to a difference of circumstances? Does he fear that this stretch of materialism, this act of philosophical consistency, or his neglect to abjure the obvious inference, may impair our confidence in the apparently though not really less objectionable scheme of reducing organic life to the virtual condition of the simple elements of matter, and thus fail of inculcating the most dangerous atheism by attributing creative power to those elements (§ 14, c)?

 $350\frac{3}{4}$, gg. But let us hear the chemist upon this interesting point. And Liebig, first; who, also, shall show that no injustice is done by

the preceding remarks. Thus:

"The higher phenomena of BIG's Animal Chemistry.

"Physiology has sufficiently demental existence cannot, in the cisive grounds for the opinion that present state of science, be referred every thought, every sensation, is to their proximate, and still less to accompanied by a change in the their ultimate causes. We only composition of the substance of the know of them that they exist. brain; that every motion, every We ascribe them to an immaterial manifestation of force, is the REagency, and that, in so far as its sult of a transformation of the manifestations are connected with structure or of its substance."—Ib.

matter, an agency entirely distinct "Thought, sensation," &c., are from the vital force, with which "manifestations of force," and are, it has nothing in common."—Lie- therefore, "the result of," &c. See Parallels, p. 158, no. $5\frac{1}{2}$.)

And now the other able and distinguished chief:

^{*} See my "Notice of Reviews," ut cit., and my "Examination of Reviews," p. 43, 44, in "Commentaries," vol. iii.

"I will not venture to raise the veil, by which the action of the nerves, or the higher functions of the mind, have hitherto been shrouded from observation. As man has an immaterial and immortal part, which is identical with his real being, and of which alone he will consist, when the material frame by which he is bound to the earth, shall be dissolved; and, as the inferior animals possess, in common with man, certain powers of perception, associated with certain appropriate organs, whose functions have no connection with consciousness; so do animals and plants perform in common a great many operations which are distinct from both of those now mentioned, or which, at least, have their origin in distinct causes.

"It is only the LATTER CLASS of which I speak, and to which I apply the general term of organic life. To that subject I shall restrict my

remarks."—MÜLDER, ut cit.

Now, I say, 1st. Why not "raise the veil from the action of the nerves" in a professed work on physiology, and a work, too, which would revolutionize the science? Have you no phenomena to guide you in "raising the veil?" Do you fear their contact with the phenomena of the laboratory? Is it right to make this declaration, and then to refer a vast series of phenomena exclusively to "organic life," which could have had no existence without the "action of the nerves" (see § 350, no. $18\frac{1}{2}$)? I deny, too, 2d, that "the higher functions of the mind have hitherto been shrouded from observation;" and I am supported by all who truly believe in the independent existence of mind, in the affirmation that its "functions" are characterized by an infinitely greater variety of unique phenomena than are the processes of inorganic nature. There is no "veil to be raised" in this or the other case. It is, indeed, by the recognition of these phenomena that our author feels obliged to admit the existence of "an immaterial part," however inconsistent the simultaneous declaration that "the functions of the mind have hitherto been shrouded from observation." And, I am alike sustained, also, and by every dictate of philosophy, in the conclusion that, if the phenomena of mind are decisive of the existence of "an immaterial part," so are the far more varied, and numerous, and equally unique phenomena of organic processes, conclusive of the existence of some not less peculiar force, power, or "immaterial" or material "part," upon which they depend. In any event, however, the physiologist has a right to insist that the chemist shall not reject all considerations relative to the "action of the nerves," when he invades organic nature with retorts, crucibles, acids, &c.

"Analogy is," undoubtedly, as Bacon says, "the basis of all the sciences." Nature, throughout, is bound together by analogies. The principle reaches from the Creator to the mind of man, to his "immaterial and immortal part." And so it does from the force and the properties of life to those of dead matter. Here is the delusion of the chemist. But, there is even a wider difference between the formative principle of life and destructive chemical affinity, than there is between the Creative Spirit of God and the created, dependent

spirit of man (§ 1076).

3503, h. The grand characteristic of organic life is the principle of life, capable of imparting that principle to matter which is destitute of it, and which it retains only while in its proper connection with the being by which it was so endowed. The doctrine which refers the

properties of life to the elements of matter is atheistical in its application (§ 14 c, 74, 175); and the recognition, simultaneously, of a "Creative Power," is but another conventional word for nature, or designed to protect the doctrine against the fatal imputation of irreligion (§ 64, h). That imputation, however, is indelibly stamped by nature herself. The mode of defense is well shown in the late highly lauded and popular work on the "Vestiges of the Natural History of Creation," in which the author considers La Place's infidelity as to the modus operandi of matter in forming the Universe, and the doctrine of spontaneous generation in its most ample extent. The author's defense of Mr. Crosse's creation of animals out of silex is a good example of the specious reasoning by which so many are cheated into projects which contemplate the worst results to philosophy and religion.* Thus:

3503, i. "The supposition of impiety arises from an entire misconception of what is implied by an aboriginal creation of insects. The experimentalist could never be considered as the author of the existence of these creatures except by the most unreasoning ignorance. The utmost that can be claimed for, or imputed to him, is, that he arranged the natural conditions under which the true creative energy, that of the Divine Author of all things, was pleased to work in this instance. On the hypothesis here brought forward, the Acarus Crossus [!] was a type of being ordained from the beginning, and destined to be realized under certain physical conditions. When a human brought these conditions into the proper arrangement, it did an act akin to hundreds of familiar ones which we execute every day, and which are followed by natural results, but it did nothing more." The defense of La Place's system proceeds upon the same specious assumption (p. 910-911, § 1083, p. 921-928, § 1085).

Now the foregoing doctrine transcends not only the usual geological hypothesis of a successive creation of animals, but that, also, of spontaneous generation; both of which are, of course, anti-Mosaic, and regardless of the established order of creation (§ 303 a, 303). But here we have an exemplification of a strictly atheistical expedient, in the attempt to assign the existence even of organic beings to the merest chance, under the pretext of ascribing to that chance the intrinsic attributes of a Creative Power, and the imposing title of "the Divine Author of all things"! It is the same with each and all who allow a God, a Creator, &c., yet reject entirely His Revelation as to creation, supported as it is by the most consummate and endless systems of Design. It is the old expedient of the wolf in the disguise

of the sheep (§ 14 c, 64 h, 74, 733 d).

3503, k. Nevertheless, the foregoing work is powerfully sustained by able articles in the British and Foreign Medical Review for January, 1845, consisting of twenty-six pages of eulogistic remarks; and in the Medico-Chirurgical Review for the same month, of ten pages not less congratulatory. The work was published late in 1844, and, although not at all relevant to medicine, it was taken up with avidity by the two leading medical journals of Europe, and an effort

^{*} See Medical and Physiological Commentaries, vol. i., p. 707; vol. ii., p. 96. In vol. i., Grass is a typographical error for Crosse. It is also possible that the "created animals,' instead of being "crystalized spiculæ," were real animals evolved by the action of galvansim from ova contained in the water (see § 74, 188½ d).

made to prepossess the medical profession before the work itself should fall under their observation; observing in this respect the system which was almost universally pursued by the periodical press

even in anticipation of Liebig's work on Animal Chemistry.

In my Essay on Spontaneous Generation, embraced in the Medical and Physiological Commentaries, I have had occasion to refer to the charge of infidelity which is often laid against the Medical Profession. I have there, too, defended that Profession against so great an injustice, and have held responsible the proper Sources that have given rise to this imputation. I have also shown that that imputation is greatly due to the cultivation of the chemical and physical hypotheses of life, to which the foregoing Reviews have been laboriously devoted. In conclusion of the whole matter I have said that,

"The steps are gradual from the incipient errors in natural philosophy to a disbelief in the Mosaic Record of Creation. When we have ultimately reached the brink of the precipice, there is but one dreadful plunge, and we are then in the vortex of atheism. We may begin, as I have said, by a simple denial of the living powers of organized beings, when it will become, at last, an easy argument upon this, and analogous premises, that the Almighty had but very little, if

any agency, in the most sublime part of existences."

"Let philosophy interrogate nature to its fullest satiety, under the direction of its Heaven-born principles; but let it be consistent, and maintain its dignity. And should it sometimes, as it must in its wide range of nature, come in contact with miracle, that is its limit, contented that it begins at the confines of Creation; yet still may it stretch into the regions of Eternity, past and to come; but now it is employed in its nobler work of sacrificing its relations to second causes, and in establishing relations with the First Cause of All."

-Medical and Physiological Commentaries, vol. ii., p. 140.

 $350\frac{3}{4}$, kk. It is now my purpose to quote the foregoing Reviews in connection with the "Vestiges of Creation," partly for the object just assigned, and in part to supply other examples in justification of what I have said in behalf of the Profession, and of the tendency of the chemical and physical hypotheses of life and disease to lay the foundation of a grosser materialism, and of infidelity in Religion (§ 175). It seems peculiarly appropriate that Reviewers, who wield an extensive and powerful sway, and whose occupation it is to defame whatever molests that dominion, should be used for the contemplated purpose, and this, more especially, as both Reviewers offer defiance to the "Saints," and the "timid religionists." The Reviews are conducted with great diligence and research. Their influence is coextensive with medicine. That influence must be sapped by a display of its tendencies. There can be no difficulty with a defense of the right. The inculpated are able, their means ample, their coadjutors numerous and powerful, the public generous, and, as I said on a like occasion in the Commentaries, "I am single-handed, and have nothing but facts for my weapons" (vol. i., p. 391).—Note W p. 1127.

Infidelity is certainly a term which should be well sustained in its application; better, at least, than when applied to myself by the first of the following journals (see Examination of Reviews, p. 84-88). As it respects the Reviewers, the imputation appears to be invited and expected, as an obvious consequence of the doctrines advanced:

and, although I do not belong to the denomination of "Saints," or of the "timid religionists," it is not less my duty as a man, and as an expounder of the Institutes of Nature, to bring those institutions to operate upon infidelity. There can be no place more appropriate for looking "through Nature up to Nature's God," than in the general survey of organic beings. If ordained in their organization and their laws by a higher Power, that organization and those laws may well be urged in proof of their Origin. Then, too, shall the minister of health realize the importance of the Institutes of Medicine, and the spirit of the Hippocratic maxim, that "a philosophical physician is like a god."

I shall quote a passage of general import from each of the foregoing Reviewers, that no doubt may linger upon the mind of any reader as to the justice of the criticism which I have now exercised in behalf of religion, of morality, of the dignity of medicine. The *emphasis* is mine.

And first the elder brother; beginning thus:

"This is a remarkable volume, small in compass, but embracing a wide range of inquiry from worlds beyond the visible starry firmament, to the minutest structures of man and animals. No name is prefixed,—perhaps in order to avoid the snarls of the narrow-minded and bigoted saints of the present day," &c.

The middle thus:

"For how many millions and millions of years this production and reproduction of animals went on before man made his appearance on the scene, no human being will ever know. [!] In all probability, countless ages must have elapsed, before this master-piece of creation appeared. Our author's speculations on the how, the why, the when, and the wherefore this great event occurred, will not give satisfaction to the present race of mankind. [!] His hypothesis is three or four centuries in advance of the TIMES, and will be stigmatized by the modern SAINTS as downright atheism," &c.

And the end, thus:

"We have dedicated a space to this remarkable work that may induce many of our readers to peruse the original. The author is decidedly a man of great information and reflection. He will have a host of saints in array against him, and many will join in the cry, from hypocrisy and self-interest. As we said before, his doctrines have come out a century before their time."—Medico-Chirurgical Review, p. 147, 153, 157. London, Jan., 1846.

Next, Dr. Forbes, in the British and Foreign Medical Review.

"This is a very beautiful and a very interesting book. Its theme is one of the grandest that can occupy human thought,—no less than the Creation of the Universe." "We are also influenced by the abstract desire to place before our readers matter for their contemplation, which cannot fail at once to elevate, to gratify, and to enrich the mind. It has always been one of the boasts of our noble profession that it touches and blends with every science; and we should be sorry that our humble efforts should at any time be wanting to stimulate its professors to exertions that might still justify the boast"!

Of La Place's nebular hypothesis, he says:

"So far from admitting the atheistical tendency which TIMID RELIGIONISTS have attributed to the nebular hypothesis, we consider it the grandest contribution which Science has yet made to Religion," &c.

The reader, therefore, will have no difficulty in understanding the "conventional" nature of certain phrases in the following remarks by

Dr. Forbes. (See h.)

"That the Creator formed man out of the dust of the earth, we have scriptural authority for believing, and we must confess our own predilection for the idea, [!] that, at a period however remotely antecedent, the Creator endowed certain forms of inorganic matter with the PROPERTIES REQUISITE TO ENABLE THEM TO COMBINE, AT THE FITTING SEASON, INTO THE HUMAN ORGANISM, [!!] over that which would lead us to regard the great-grand-father of our common progenitor as a chimpanzee or an orang-outang."—BRITISH AND FOREIGN MEDICAL REVIEW, p. 155, 158, 180. London, January, 1846. (See l.)

The author of the Vestiges of the Natural History of Creation is

thus quoted by Dr. Forbes:

"We have seen powerful evidence that the construction of this globe and its associates, and, inferentially, that of all the other globes of space, was the result, not of any immediate or personal exertion of the Deity, but of NATURAL LAWS which are expressions of His will. What is to hinder our supposing that the organic creation is also a result of NATURAL LAWS which are, in like manner, an expression of His will?"—NATURAL HISTORY OF CREATION.

Upon the foregoing extract, which is a part of a more extended

one of the same nature, Dr. Forbes remarks, that,

"The complete accordance of these views with those some time ago propounded by ourselves (vol. v., p. 342), must be evident, we think, to our readers. To the objection which some time religionists may urge against them, that they are inconsistent with the Mosaic record, we simply reply with our author, that we do not think it right to adduce that record either in support of, or in objection to, any scientific hypothesis, based upon the phenomena of nature," &c.!—British and Foreign Medical Review, p. 167.—Note Pp p. 1142.

Dr. Forbes assumes, of course, that all the misapprehensions and perversions of "the phenomena of nature" are paramount to any thing declared in the Mosaic Record (\S $5\frac{1}{4}$, 74, 733 d, 1079 b, 1085).

The most superficial reader cannot fail of discerning in the foregoing principles, as in many other analogous instances, the motives which have induced those foremost medical Reviews to lend their powerful aid in propagating the materialism of Carpenter, the absurdities of Liebig, the humoralism of Andral, and the putrid anatomy of Louis, and of their respective schools; and why, on the other hand, they have been equally regardless of truth in their vocation as critics on the labors, the researches, and the statements of others.—Note W

350³/₄, l. I have already shown in this and other works how convenient a matter it is for "the properties of life in the elements of matter" to bring these elements into an organic state. And since I am now on the subject of the first and greatest step in the process of vivification, it may be useful, as it is appropriate, to show how the advocates of "the properties of life in the elements of matter," and the propagators of spontaneous generation, and eminent geologists who promulgate a successive creation of animals according to their scale in organic nature and in conformity with the development of new physical agencies, ay, and certain eminent vitalists whose otherwise sound philosophy should have enlightened them as to the Great First

Cause—in view of all these things, I say, it may be conducive to sound physiology to show how the foregoing schemers of "creation" arrive, in part, at least, at the conversion of organic matter into the complex fabric, after that matter shall have been duly compounded by "the properties of life which reside in the elements." For this purpose I will take the statement of the distinguished vitalist Tiedemann. Thus,

"The most probable hypothesis is, that the substance of organic bodies existed primitively in water, as matter of a particular kind, and that it was thereendowed with the plastic faculty; that is to say, with the power of acquiring, by degrees, different simple forms of living bodies, with the concurrence of the general influences of light, heat, and perhaps also of electricity, &c., and of then passing from the simple forms to other more complicated; varying in proportion to the modification occurring in the external influences, until the point when each species acquired duration by the production and manifestation of activity of the genital organs"!—Tiedemann's Physiology of Man.

That is the doctrine, candidly avowed by those to whom genius and the conviction of a right discernment of the ways of nature impart a fearless independence, however it may be disguised by others under the "conventional term" of creation. But, Tiedemann is a philosophical vitalist, and did not confound the principle of life with the forces of inorganic matter, nor, like Carpenter, Fletcher, Prichard, Roberton, Forbes, &c., place the properties of that principle in the elements of matter. He started with matter in more or less of an organic state, and leaves it problematical how its elements became united into that peculiar vital compound. He did not even imply that the elements being so endowed could organize themselves, for he adds to the forcgoing statement, that,

"Although we cannot here answer the question, whence came the water and 'he organic matter which it contained, yet this hypothesis is the one which accords best with the facts with which geology has lately been enriched." And again, "If it be asked, whence organic matters proceed, how they are produced, together with the power of formation inherent in them, we are necessitated candidly to confess our ignorance on the subject, inasmuch as the first origin of organic matters and living bodies is altogether beyond the range of experi-

ment."-TIEDEMANN'S Physiology of Man, p. 14, 193.

It will be thus seen that even Tiedemann's doctrine enjoys "a loophole" which cannot be allowed to those who place "the properties of life in the elements of matter," or who endeavor, or propose, to cre ate organic compounds in the laboratory of the chemist; since, in respect to the latter, were the production of organic compounds within "the range of experiment," the accidental nature of the origin of such compounds, and, therefore, the incipient being of man, would be established by the laboratory. And now I ask, does not the organic chemist attempt or profess to create organic compounds? So says Liebig, § 350, no. 39, and so say most other distinguished chemists. Liebig and his disciples create the compounds; Crosse and his followers create the animal. Others do but make the attempt; and this is a very numerous class who thus enter into competition with the Original Author of organic compounds. What, therefore, is the difference in principle between him who pretends to have succeeded

in this work of creation, and the other who has attempted the work. but without success?

From the physiologist who advocates the existence of "the proper-

ties of life in the elements of matter," we hear that,

"There is no reasonable ground for doubt that if the elements could be brought together in their requisite states and proportions by the hand of man, the result (artificial organic compound) would be the same as the natural compound." Again, "that the germs (of parasitic plants and animals in the interior of others) have been conveyed from without into the situations where they are developed, must be held as a very forced supposition" !- CARPENTER'S Principles of General and Comparative Physiology, p. 146, 395; also, this work, § 14 c, 175 c, d, 189 b.—See doctrine of "Development" p. 922, and Note Pr p. 1142.

3503, m. Mülder has the manliness to carry out the obvious tendency of his doctrines, which may be expressed in a brief quotation.

"Upon the principles which have been stated, no room is left for the dispute as to equivocal generation and epigenesis." Nevertheless, it is allowed by Mülder that cellular structure "cannot yet be imitated by art." But, waving this conceded difficulty, if the physiological arguments which I have advanced in section 14 c, as to a real Creator, can be invalidated, I shall concede that a ground has been obtained for the doctrine of spontaneous generation (§ 1051, p. 922, § 1085).

3503, n. As I shall soon dismiss this author, it may be useful, in consideration of his exalted worth as a chemist, and his authority among physiologists, to show that even one who endeavors to hold a consistent philosophy on the subject of chemical physiology, yet sees in organic beings so much to contradict his chemical doctrines, that he evinces the usual inconsistency of those who have endeavored to confound the science of life with that of chemistry ($\S 4\frac{1}{2}, d$). For this purpose I shall select two passages only, and place them in parallel columns, after the manner adopted in relation to Liebig in section 350. I shall elect, also, for the negative side, a passage which will show, what cannot be too often repeated, that the chemists are absolutely regardless of their own fundamental doctrine, of "ascending from phenomena to their causes," by rejecting all the unique phenomena of life as indicative of any peculiar force or laws. The affirmative side, however, is all that the vitalist desires (§ 189).

Denial of the Vital Principle and Recognition of the Vital Principle Vital Properties. and Vital Properties.

"Wherever forces are found in organic nature, there are substances which are all supplied with molecular CHEMICAL FORCES. Even those singular structures, the nerves, consist of the same elements as the ordinary substances which these organic forces are of the organic kingdom. It is made weaker? Neither is imthus undeniable, that the MOLECU- probable. Every thing which LAR FORCES act a chief part in the organism, so far as a change of PRINCIPLE, becomes incapable of substances takes place therein; being stimulated by the VITAL

"The question is, whether, during decomposition, the organic FORCES grow weaker of themselves, permitting the elements to obey their primary tendency,-or whether causes must exist by ceases to be subject to the VITAL

and that NO GENERAL, NO VITAL FORCE, should be assumed as the source of those molecular forces. Such a vital force is irreconcilable with the true principles of science, which require that nothing should be assumed as existing, but that every thing should be sought for in nature; which teach us to ascend only from an unprejudiced consideration of the phenomena to their causes, and to assign those causes only as we deduce them from the observed phenomena." -Mulder's Chemistry of Vegetable and Animal Physiology, p. 68. 1845.

FORCES; -it is placed in other circumstances; and as the PROD-UCTS OF THE VITAL FUNCTIONS ARE DIFFERENT FROM THE PROD-UCTS OF INORGANIC NATURE, in consequence of the very difference of the circumstances ir. which the elements are placed, so the products of substances, deprived of VITAL INFLUENCE, must also GREATLY VARY with circumstances. Hence it may happen, that THE FORCES present in organic substances, when deprived of the VITAL INFLUENCE, may DISAP-PEAR of themselves. The impression they had at first received is changed, modified, OBLITERATED and therefore the effects can no longer be the same. A substance persists in the state into which it was first put, according to the law of INERTIA; but the maxim, sublata causa tollitur effectus, is of EQUAL VALUE."—MÜLDER'S Chemistry of Vegetable and Animal Physiology, p. 54 (§ 59).

I shall conclude with an extract from Mülder, in which it will be seen that he has adopted the method set forth by myself in my Essay, on the Philosophy of Vitality' (1842), of investigating the subject in the development of the germ. It may be useful to place in contrast the purely chemical and the purely vital interpretations of that development (§ 65). I may also premise that it should be observed that the chemist keeps out of view all the remarkable circumstances attending the development of the egg which I have set forth as irreconcilable with chemical phenomena, and limits himself to statements founded on a supposed analogy with the simple results of chemical affinity as observed in inorganic nature. Thus:

"If we review the phenomena of life, caused by change of materials, we must go back to the original formation of organs—to the growth of an individual from a germ." After illustrating the develment of the germ by "an example from the inorganic kingdom" (the formation of prisms from a solution of the sulphate of soda!), this

distinguished chemist proceeds to say, that

"Undoubtedly the differences which exist between the particles of the same organic substances are not chemical, in the ordinary gross signification, but are of the nature of those which are connected with polymorphism. The chemist gives us but a rude result—the composition in a hundred parts, frequently not affording us any insight into either the real characters of substances, or into their real differences. Whenever such dissimilar particles come together, a compound must be produced, possessing peculiar forces, which, though dependent upon the molecular forces of the elements, are yet not determined by these alone. The new arrangement causes a modification of those primary forces. Whenever it takes place, they appear modified, and therefore indicate their presence by producing new effects. In sulphate of soda, the whole collected forces of its constituent molecules—those of sulphur, sodium, and oxygen—are still existent; and upon these alone depend its qualities, composition, and crystaline form. Sulphate of soda cannot possess other qualities—cannot become other in property—than what results from its elements, and exclusively originates in these.

"Thus, then, we suppose that the molecules of the substances in the embryo are arranged, in the first place, simply, and afterward more complexly. Not a trace of any organ is as yet perceptible, however; nor of any force, therefore, by which these organs will be governed. By the new arrangement of the particles, the molecular forces are modified anew, and this process is continuous. Although the primary forces, once united with the materials, remain the source of every action, of every manifestation of phenomena, of every chemical and organic, that is, physical, combination; they must, nevertheless, produce different effects, as the combinations become more complex. existing particle is the germ of a subsequent one, which is more complex; and, while the temperature necessary for hatching keeps the primary forces always excited, there is originated in the new arrangement of the particles, and also in the forces proceeding from the groups recently formed, a modification of these primary forces, which is constantly on the increase.

"The whole material of the embryo in the egg is gradually brought in this manner within the circle of action. Then the circle is still more extended, and in its action are comprehended the elements of the yolk, and also of the albumen. These are erroneously called the food of the newly-formed chicken, or its rudiments. In these elements there are forces also conjoined with the materials—chemical forces, analogous to those which exist in the embryo, and contributing to the production of the whole. These forces differ from those found in the embryo, not in nature, but only in direction, or in the mode of

manifestation."—MÜLDER, ut cit, p. 71-73.

351. Having in the preceding sections, as well as at other times, summoned, in behalf of truth, and of the noblest institutions of nature, an adverse party, and having shown, not only by the nature of the pursuits which engage the whole practical attention of the leaders of that party, but by an open cross-examination of the acknowledged chiefs, that the entire field of physiology and medicine remains, as ever, in sole possession of those who are employed in its cultivation, and that, by no possible accident, fraud, or conspiracy, can it be transformed or transferred into the laboratory of the chemist, I shall proceed to a more critical examination of the philosophy of digestion, both in its vital, and its supposed chemical attributes.

352. All other processes of living beings, whether animal or vegetable, and especially the whole work of assimilation after the entrance of the food within the lacteals, being exclusively vital, it follows, as a great analogy of nature, that the first step in the process of assimila-

tion is equally due to vital influences (§ 323-326).

353. Since every species of complex animals has some peculiarity of

organization, not only of the alimentary canal, but of the liver, salivary glands, pancreas, teeth, jaw, skeleton, muscles, and also of instinct, corresponding with a certain modification of the vital endowments of the gastric juice in each species of animal, which shall be exactly, and forever, and undeviatingly suited to the digestion of those kinds of food which were ordained by the Creator for the sustenance of each when He thus wonderfully instituted this almost endless system of exact Designs; each individual part having its specific final cause, each final cause modified in every species and with corresponding peculiarities of organization, and all concurring to one great final cause of subserving those exigencies of life which are fulfilled by the gastric juice, and whose modifications in different species of animals harmonize with the special attributes of all the concurring causes, and so suited by Infinite Wisdom to the nature of the food of every animal, that its incipient change shall be one of assimilation to the nature of the being, yet nearly coincident in all animals from the general coincidence in all organic compounds; I say, in all this labyrinth of Designs, so exactly modified in every species, yet correspondent in all, and each and all, in their individuality, their variety, their modifications, and their unity of purpose, having a specific reference to the alimentary material of each species of animal, we see in perpetual progress what is equivalent to a never-ending voice from Heaven, proclaiming that the organic stomach has no parallel in its capabilities and results in the inorganic world, or in the laboratory of the chemist. But this is not all; nor will I fail to convert the stupendous whole, as I advance with the details of assimilation, to the fundamental philosophy of organic life.

354. The constituent elements of the food having been subjected to special transformations, and imbued with the first gradations of life, by the vital action of the salivary and gastric juice, and perhaps, also, by contact with the stomach, is thus converted, in all animals, into apparently one and the same homogeneous product. It is then submitted to the farther organizing effects of the bile and pancreatic juice, passed through the wonderfully vivifying lacteals, carried forward and subjected to the whole animating influence of the pulmonary system, perfected in its exalted endowments by the whole labyrinth of the circulatory organs, and, lastly, though not least, the various compounds are determined, each and all, from that one homogeneous fluid, and in one everlastingly exact manner, and according to the nature of each part, by other complex living systems, and thus perpetuated forever in all their exact varieties,—but how, no imagination can form the most remote conception, but through the instrumentality of those specific properties of life which were the only power concerned from the beginning to the ending of the astonishing series of unvarying changes (§ 42); and, however it be that each ultimate product is destined for the immediate uses of the individual, it is undeniable that the great final cause of every step in the assimilating process, till it results in the formation of blood, is the reproduction of gastric juice for the maintenance of an unceasing supply to the exigencies of organic life, and the perpetuation of the species (§ 41, 323-326).

355. The gastric juice being designed to prepare the material for the formation of blood has its powers so constituted as to be merely an agent. The blood, being the pabulum vitæ fully prepared for the

regeneration of the gastric juice, as well as of other organic compounds (§ 354), is mostly a substance acted upon by the living solids, or by the ovum-cell, just as the food had been by the gastric juice, while it serves, also, as a stimulus to the vascular parts, and is highly endowed with the properties of life to facilitate its conversion into living solids or fluids, and to make its presence in the blood-vessels compat-

ible with their life.—Note R p. 1123.

356, a. While we are thus employed in describing the various details of assimilation, attention is unavoidably arrested by the magnificence of its unique philosophy, and by the ultimate aim of every detail of all the immense variety (§ 353-355), even excretion itself (§ 412, &c.), at the production of gastric juice! And as we penetrate the more latent, but yet more impressive physiological laws to which that juice is obedient, we rise in admiration of the preliminary means of their fulfillment; and now again addressing myself to the chemist, I ask him as a philosopher, as one who would protect the consistency of his own science, what can be more emphatically significant of the abstraction of digestion from chemical agencies than the fact that the nervous power so modifies the vital constitution of the gastric juice that it fails of its usual function when a division is made of the pneumogastric nerve? Imagination can surmise no connection between the nervous power and the processes of chemistry. And yet do the writings of Liebig, and of other organic chemists, abound with assumptions that the supposed affinities of chemistry, as operative in animals, are subject to the nervous power! though it is conceded that the nearly coincident processes and results in plants sustain no such nervous influences (§ 500, nn). "The animal organism," says Liebig, truly, "is a higher kind of vegetable." To suppose that such powers operate in harmony together, and that the mind or its passions are capable of influencing, extensively, the operation of chemical forces, in constantly modifying the various secreted products, both as to quality and quantity, is a positive violation of the most obvious and universal rules in natural philosophy (§ 455 a, 461, 478 b, $488\frac{1}{2}$, 493 cc, 893 a, c, $893\frac{1}{2}$).

356, \dot{b} . It is evident that a great difficulty exists with many, who admit a principle of life in relation to the solids, in imagining a fluid to be equally endowed, and alike capable through that principle of acting upon organic matter. But we must take the facts as we find them, nor allow inorganic nature the slightest interference. If analogies must be had, let us seek them in the organic being, and we shall be certain of success. In the instance before us we have the admitted vitality of the blood; but, unlike the gastric juice, it produces no changes in matter. We have, however, the simple ovum, "whose vital properties," in the language of Dr. Carpenter, "confer upon it the means of itself assimilating, and thereby organizing and endowing with vitality the materials supplied by the inorganic world" (§ 64, g). Here, then, the analogy is remarkably forcible, and the more so, as the fact is conceded by the strictly chemical school of digestion. So, of the semen, in another aspect of the active condition of the principle of life in an organic fluid; this substance, through that principle, being capable of modifying the organic constitution of the ovum in such wise, that the offspring shall inherit the intellectual, vital, and physical peculiarities of the male parent, with six fingers instead of five (§ 72, 73). tion consists in the remarkable endowments of the stomach, as manifested by its vital signs, and by the sympathies which prevail between this organ and all other parts. The final cause of this peculiar constitution of the stomach, this lavish supply of the properties of life, this subservience of other organs to its dominion, must be sought in its adaptation to the generation of a fluid that may bestow the first and most difficult act of vitalization upon dead matter (§ 356, a). There would also have been something harsh and abrupt in nature to have admitted into the recesses of her living organization mere dead mat-It is opposed to all analogy, and is, therefore, opposed to all reason. But, that a fluid should perform this astonishing office, this first and great step in the ascending series, it must possess in a high degree the principle of life. Mysterious as it may be represented, we must all of us come at last to the admission of the existence of a vital principle; yet far less mysterious, and far less difficult of comprehension than the human soul. It is fair, then, to conclude that an organ destined for such a high function should possess that principle, in common with all other parts, as the means on which its function depends; and the best evidences in favor of this analogical inference are

to be seen in its diversified manifestations of life.

358. We have seen, also, that it is conceded by philosophers who defend, in extenso, the chemical hypothesis of life, that there may be something appertaining to the stomach totally distinct from the chemical powers, and which is capable of imbuing the chyme with vitality and an organic condition; and it is, therefore, quite a philosophical conclusion that this vital something has an important agency in preparing the material for the admitted exercise upon it of the vivifying or organizing power. Nor can there be any valid objection to the supposition that this vitalizing power, which so far transcends the chemical forces in the organizing effect it is allowed to exert, may be fully adequate to any transmutations the food may undergo; and this inference is the more corroborated by the consideration that matter already in an organic state must be better fitted for the process of vivification than it can possibly be after its elements are broken up and recombined by forces with which those of life are in absolute opposition. Besides, the vitality of the gastric juice, or the vital influence of the stomach itself, being fully admitted, and even capable of organizing the food anew, should sufficiently protect the alimentary matter against any chemical agencies which have been supposed to operate. That this counteracting power, indeed, prevails to the full extent which I have alleged, appears to be rendered certain by the ordinary absence of any of those chemical changes which take place where numerous substances are mixed together out of the stomachsubstances which often possess strong chemical affinities for each other, and whose operation within the stomach would be promoted by its high temperature. On the contrary, whatever the variety, it is uniformly resolved into one and the same homogeneous substance, utterly unlike the results of chemical reactions of one kind of food upon other kinds; and what is also as conclusive as it is astonishing, the chyle is apparently the same substance in all animals. Chemistry must here be consistent with itself, and not renounce, for the sake of hypothesis, those precise laws by which, in its legitimate pursuit, it lays open, with astonishing exactness, what had appeared the arcana

of nature. Here, too, upon the chemico-physiological hypothesis, is presented an instance in which it is necessarily assumed that the properties of life and the forces of chemistry act together in concert in converting dead into living matter—one destroying, and at the same moment the other vitalizing! while the assumption is contradicted by all that is known of the relation of these forces to each other (§ 301, 338, 360, 436).

Nor may we lose sight of the demand of philosophy not to multiply causes where one is perfectly adequate; and especially where it is admitted that all the others are of themselves wholly inadequate.

359. The last remark may be also equally applied to a common assumption which is set forth in the following apparently plausible manner: "The vitalists," says one of their opponents, "are loath to admit the operation of chemical agents at all, and would seem to consider it derogatory to suppose that any changes, save the subtle ones effected by the powers of life, are worked upon the aliment." "The vital principle," he says, "whatever it may be, incessantly makes use of chemical and mechanical agents for its purposes; and it is no more degrading to it to employ an acid liquid, and a triturating process, in order to digest the aliment, than it was to have recourse to bony lev-

ers, cartilaginous pulleys, and tendonous ropes."

Here, in the first place, will be observed an entire begging of the question as to digestion by an acid, since that has never been shown, and is the main point at issue. It is a perfectly unfounded and extorted inference from the factitious analogy supposed to be seen in the admitted mechanical movement of the food in the stomach, bony levers, cartilaginous pulleys, &c. But the pretended analogy, I say, is utterly inapplicable, were it admissible to reason from better premises of this nature to the existence of important facts which have no other foundation. The bony levers, muscles, tendons, heart, and large blood-vessels, are mere instruments acted upon by the vital principle, and have no part in the vital results, except as they are the passive instruments of the properties of life. The same distinction exists between the process of digestion, and the mechanical movement of the food in the stomach, or the "trituration" of the food, as it is erroneously called by the writer just quoted; since food is not triturated by the stomach excepting where that organ is designed to supply the place of teeth. There exists, I say, a total want of analogy between that mechanical movement of the food and the assumed action of an acid; since, in the latter case, a radical change is supposed to be wrought in the alimentary mass, while no such change is wrought by the mere movement, or even by the trituration or grinding of food in the stomach. The contractions of the stomach, which are purely of a vital nature, facilitate the process of digestion; but they do no more than to expose the food freely to the action of the gastric juice, by which, alone, the conversion into chyme is performed. The contractions, or "trituration," are exactly on a par, as auxiliaries to digestion, with the teeth, or with the knife, which divide the food. The acid alone applies to the supposed chemical process of chymification. This is the only agent, involving the only force distinct from the vital principle that is supposed to operate, and to take part with the properties of life in the functions which belong to these properties. Nor is this all. Those chemical forces, or an equivalent agent, are supposed to a pertain to the gastric juice (a product of the most highly endowed organ in the animal system); and through that product, and by that product, to operate independently of the vital properties, or, under their control. But, here it may be again affirmed that throughout nature there is not an analogical fact to warrant the conclusion; and with equal truth it may be said that there is nothing to aid our conception of the co-operation of the chemical and vital forces, while all that is known of their relations to each other proclaims their absolute independence.—Med. Chirurg. Rev. Lond. vol. 29, p. 107.

360. But, again, it is the admitted final cause of the gastric juice to bestow life upon dead matter, while it is incontrovertible that inorganic matter is insusceptible of any such influence from gastric action, Every fact proclaims that nature has provided the vegetable kingdom for the purpose, especially, of determining organic combinations out of inorganic substances for the sustenance of animal life. In the language of Liebig, "The first substance capable of affording nutriment to animals is the LAST product of the CREATIVE ENERGY"—ay, "the CREATIVE ENERGY," he says, " of vegetables."—(Animal Chemistry.) It is manifest, therefore, that it would be an absurdity on the part of nature to have ordained that chemical agencies should operate even at the very threshold of life, at the very fountain for which she had provided elaborate means to subvert the combinations of chemistry, and to bring them into those entirely new arrangements that approximate the changes they are destined to undergo in the animal stomach. And far less probable is it, that this fundamental principle should be lost as we ascend from vegetable to animal organization; since every chemical result within the stomach would tend to reduce the aliment to the state of that inorganic matter whose complete reduction into organic compounds was effected by the vegetable kingdom for the uses of the animal. Such chemical results, therefore, would counteract the great final cause of nature, in either organic kingdom; and, in the animal, would render the means of sustenance more and more indigestible, and progressively liable to the condition of inorganic matter (§ 338).* This is fully allowed by the chief of the school of pure chemistry, as shown in the foregoing parallel quotations. Take another summary statement, than which nothing can be more contradictory of the chemical rationale. "While no part of an organized being," says Liebig, "can serve as food to vegetables, until, by the process of putrefaction and decay, it has assumed the form of inorganic matter, the animal organism requires, for its support and development, highly-organized atoms. The food of all animals, in all circumstances, consists of parts of organisms."—(Animal Chemistry.) Chemical philosophy should consider that nutriment of an animal nature requires but little more than the solvent process, and the bestowment of vital properties; while, in accordance with its crude hypotheses, animal compounds must be, more than vegetable, subject to disorganizing agencies, and thus more completely removed from their original and near approximation to those of the living animal (§ 18 a).

361. But again I say, if the vital principle be "capable of making use of chemical agents," no reason can be assigned why it may not be equal to the whole work of digestion, and of every other process

^{*} This argument is adopted by a writer (a distinguished chemist!) in the Amer. Journ. of Science and Arts, May, 1859, who verbally agrees with me that—"The forces of life and inorganic nature act in opposite directions, the former upward, the latter downward."—See § 301, and p. 911, § 1083. Also, p. 236, § 436.—(1860).

of living beings. The simple construction may be comprehended, while the other is utterly unintelligible. The former alone is agreeable to the rules of philosophy, and abolishes the inextricable confusion which attends the chemical hypothesis. What, indeed, can be meant, by the vital properties making use of chemical forces? Can there be a more glaring absurdity? more absolute nonsense? are those chemical forces brought into use, how held in subjection, how forever maintained in one exact operation in each particular organic process, of which there are multitudes, distinct from each other, going on in the same individual? How do they elaborate from one common, homogeneous fluid, either the blood, or the sap, all the various, unique, unchanging, secreted products of the whole organic being? Products, forever the same in every part, yet differing from each other according to the nature of the part? Did you ever hear or dream of any thing analogous to this in that inorganic world where chemistry holds its empire? When do those chemical forces begin to operate, in the living body, what part do they perform, and what is the allotment of the properties of life? Is there any known concert of action between the two species of forces? On the contrary, is it not every where demonstrated that the properties of life are in direct opposition to the forces of chemistry?

Whatever be the construction, by uniting the two forces (as is done by the only chemical school that is entitled to a respectful notice), we convert what is a simple problem, like all other processes of nature, into the greatest paradox that has been yet devised by the ingenuity of man. It is in vain to say that some one or two of the products of organization, such as carbonic acid, and urea, are such as result from chemical affinities, since these are excrementitious; while chemistry assures us that all organic compounds are utterly different in their elementary combinations from any compound of a chemical nature.

Thus might I go on to argue this subject upon general principles alone; while at every step of the argument we should see the whole chemical hypothesis of life taking its proper rank as a dream of the

imagination, or as a project of ambitious minds.

362. Digestion having been assumed to be more or less, or alto gether, a chemical affair, it rationally followed that it might be imita ted by art. Accordingly, when this ambitious science had succeeded in turning the whole inorganic world into the laboratory, it set itself at the manufacture of organic compounds, and even at the entire animal. It did not, like Alexander, sit down and weep because it had no more worlds to conquer; but, like Shakspeare, having "exhausted worlds, it then imagined new." Even eminent physiologists, who should look with jealousy upon any invasions upon the laws of nature, especially upon such as it is their peculiar province to illustrate, began the manufacture of gastric juice by fire and acids, and metallic salts. We are thus presented by these philosophers with artificial compounds, of a most incongruous nature, and we are told that each one is the gastric juice; that each is capable of the same precise results as that universal product of animals, apparently the same in all, and elaborated from the blood by an organ of the highest vital endowments, and to which there is nothing analogous in all the other products of living beings, each product being, also, equally unique, and all derived from one common source (§ 135 a, 314, 419, 827 b).

363. A diversity of opinions exists as to the real nature of the chemical agent supposed to be employed by nature in the process of digestion. Free muriatic acid having been found, or supposed to exist, in the stomach, it has been concluded by many that this must be the great agent; while Dr. Prout, and others, affirm that "free muriatic acid more or less retards the process of reduction." Dr. R. Thompson, however, states that, by digesting muscular fibre in dilute muriatic acid, he produced a substance "exactly resembling chyme." This experiment was pretty widely repeated, and many were equally successful with "dilute muriatic acid" as was Dr. Thompson. Others, on the contrary, declared their failure, and others, like Dr. Prout, maintained that this acid retarded digestion. Eberle had already advanced the hypothesis that mucous membranes, no matter whether of the stomach or the bladder, dissolved either in muriatic or acetic acid, would form the true gastric juice, and perform its wonderful operations. There is now a general bias in favor of one of these compounds, though other preparations are supposed by many to form very good gastric juice. Again, it is said that the "digestive mixture," as it has been well denominated by the manufacturers, "retains its solvent properties for months," while the gastric juice loses its solvent power soon after its abstraction from the stomach (§ 341). And what equally establishes a total difference between the "mixture" and the gastric juice is the no small circumstance that the chemist may torture and extinguish the artificial "digestive principle" in a variety of ways, and then transmute it back in all its vigor. Thus, according to Schwann and Müller, the artificial "digestive principle" may be neutralized by an alkali, and afterward "precipitated from its neutral solution by acetate of lead, and obtained again in an active state from that precipitate by means of hydro-sulphuric acid." This precipitate, we are told, when thus treated, and thus compounded of principles radically different from the original mixture, is essentially the same as the gastric juice, and that the results of such artificial preparations must be taken as the test of the physiology of natural digestion; that, abandoning nature, we must look to the resources of the laboratory for any satisfactory account of her vital processes. Nor do I at all exaggerate; for it is distinctly avowed that we knew nothing of digestion till the invention of the artificial mixtures. Thus, it is said of Schwann by one so able and distinguished as Müller, that he (Schwann) "having discovered that the infusion of dry mucous membrane with dilute acid, even after it is filtered, still retains its digestive power, the digestive principle, therefore, is clearly in solution, and the theory of digestion by contact falls to the ground." Here, a most important physiological induction is wholly founded upon a process which has not the most remote connection with organized matter.

364. I have said that the experimenters took the hint of manufacturing gastric juice from the occasional discovery of an acid in the stomach. But, this is undoubtedly a rare phenomenon in a healthy stomach, and where the food has been at all appropriate in quality and quantity. The chemical hypothesis, as I have said, was long ago in vogue, and was put at rest by demonstrative proof. Distinguished observers, Hunter, Haller, Willis, Spallanzani, Fordyce, and more recently Dumas, Schultz, and others, insist that the reputed acid is the result of a true chemical decomposition of vegetable matter.

Spallanzani, whose experiments were almost endless, Scopoli, Chevreuil, and others, rarely succeeded in finding it at all, and in some animals never. Spallanzani, indeed, affirms that the gastric juice is

neither acid nor alkaline in its natural state.

As far back as Haller's day, when this subject was agitated, it is said by this illustrious and accurate observer, that, "although there may be some rare signs of an acid in the stomach, it does not, therefore, become us to suppose that food is animalized by a chemical process; much less to compare this process with the action of an acid." And, anticipating the modern experiments with the "digestive mixture," he declares of analogous proceedings at his own era, "frustra etiam quisquam, imitatus liquores acres chemicos, liquorem corrodentem invenerit, qui carnem in pultem resolvat." And there can be no doubt that Hunter's prophecy holds good to this day, that,

"If ever any matter is formed in any of the juices secreted in any part of a vegetable or animal body similar to what arises from fermentation, we may depend on it, it arose from that process; but we may also depend on it, that there is a defect of the living principle in

these cases.'

These are not the mere speculations of genius, but the facts and the conclusions of genius after a long, and wide, and experimental survey of nature. And are these observations, nay, our own experience, our own senses, to be set aside to accommodate an hypothesis of life which identifies dead, even inorganic, with living beings?

364½. But perhaps even a greater violence, than the foregoing manufacture of gastric juice, has been recently done to physiology, in the alleged conversion, by chemical manipulations, of the secreted products of organs, totally unlike, into each other. It should be conceded, however, that this has been generally sanctioned by the journals of the day. Thus, in the London Lancet for July, 1845, is a quotation from the report of MM. Villefranche and Barreswill to the French Academy on the "Chemical Phenomena of Digestion," from which the conclusion is deduced that

"Thus, it appears easy to transform the gastric juice, the pancreatic fluid, and the saliva, into each other, and to make an artificial gastric juice from the pancreatic fluid, and vice versa"!

It appears, also, from these late experiments, that the digestive principle depends on an organic matter, that "the said matter may be destroyed by an elevated temperature," and that "its digestive powers vary, according as it is associated with a fluid having an acid or an alkaline reaction."

It would seem, therefore, not improbable that a new hypothesis will soon be in vogue, and that the acid principle will be abandoned

to satisfy the claims of new aspirants.

365. The assumed identity of the artificial products with the chyme of the human and other stomachs has never been shown in the slightest degree; and that it is the merest assumption is not only proved by what I have already set forth, but is fully admitted by those who advocate the chemical doctrine. The conclusion rests upon the mere appearance which the artificial substance offers to the eye. Thus, it is lately said by Dr. Davy, that

"It is impossible to witness the change which takes place in muscular fibre, in consequence of putrefaction giving rise to a fluid very

like chyme in appearance, without asking, may not putrefaction be concerned in digestion itself, according to the earliest theoretical notions on the subject," and as now maintained by Liebig, and his followers (§ 350)? Farther on, however, in the same work, he says, "twenty different semi-fluids might be mentioned, to which, as far as the eye can judge, this putrid matter bears as close a resemblance as

to chyme" (§ 341).

366. "Dr. Beaumont [of St. Martin celebrity] has instituted several experiments with a view to determine the power of acids in dissolving articles of food; and the results which he obtained, although they varied somewhat according to the substances employed in the experiments, have nevertheless led him to the conclusion that no other fluid produces the same effect on food which the gastric juice does, and that is the only solvent of aliment" (§ 341, 373).—Muller's Physiology,

p. 589. London, 1839.

So far Dr. Beaumont's accuracy may be readily admitted.' But, as his observations upon the natural process of digestion, as carried on in St. Martin's stomach, have become incorporated in most of the subsequent works on physiology, and even in systematic works on diet, where they generally serve as a foundation for some of the most important conclusions in the science of life, and have been seized upon with avidity by the supporters of the physical and chemical doctrines, and without any reference to their credibility, or to the unnatural condition of that celebrated stomach, it may be well to show by their conflict with universal experience, that those observations are not only worthless, but pregnant with the greatest practical errors. For this purpose, it is only necessary to present a brief abstract from the tabular view supplied by the author of the average time occupied by different alimentary substances in undergoing digestion. Thus:

ARTICLES OF DIET.						Mean Time of Chymification.	
ARTIOLES OF DIET.					Preparation.	h. m.	
Pigs' feet, soused						boiled.	1 00
Tripe, do						do.	1 00
Salmon trout, fresh						do.	1 30
Apples, sweet .						raw.	1 30
Cabbage, with vineg						raw.	2 00
Hash, meat and vege						warmed.	2 30
Goose	. , .					roasted.	2 30
Cake, sponge .						baked.	2 30
Pig						roasted.	2 30
Pork, fat and lean, re						raw or stewed.	3 00
Pork steak						broiled.	3 15
Sausage, fresh .						do.	3 20
Dumpling, apple						boiled.	3 00
Green corn and bean						do.	3 45
Bread, wheat, fresh						baked.	3 30
Do. Indian com						do.	3 15
Eggs, fresh .						boiled.	3 30
Oysters, fresh .						stewed'	3 30
Beef, fresh, lean, rar						roasted	3 00
Mutton, fresh .						do.	3 15
Fowls, domestic						do. and boiled.	4 00
Potatoes, Irish .						boiled.	3 30

Here, then, we have pigs' feet nearly four times as easy of digestion as baked bread, or roasted mutton, or beef, or domestic fowls, or eggs, or oysters; raw cabbage nearly twice as easy of digestion; roasted pig and goose a third or more easier, &c. And these are

common examples of what is known, in medicine, as "the experimental philosophy of the nineteenth century," and "the march of medical science" over all former and more rational experience (§ 18).

367. The experiments with *pepsin*, or the artificial mixtures, have been limited to substances already animalized, in their simple conditions, and in minute proportions. Hay, nuts, onions, and even arrowroot, would be appalling to *pepsin*; and the quantities of the gormand, or the variety of the epicure, would soon show the nature of

this branch of "experimental philosophy."

368. A chemical dilemma presents itself. The supposed chemical agent in digestion should be the same in all animals, to explain, in the least, the identity of the resulting products,—and so it is admitted by the advocates of one "mixture," or of another, respectively. But this, on the other hand, is clearly contradicted by the variety of the "mixtures," and by the vast variety of alimentary substances, consumed by different species of animals; while, indeed, if the least regard were paid to the laws of chemical affinity, it should be obvious that there would be no small variety of chemical influences in the stomach of omnivorous man.

369. Nevertheless, if the "digestive mixture" be made from the mucous tissue of the stomach of a strictly graminivorous animal, or even from its bladder, it will "digest" meat and other substances which form the peculiar food of carnivorous animals, but will refuse to digest most of the substances common to the animal from whose stomach the "digestive mixture" is prepared. This, therefore, is contrary to

nature.

370. Digestion is well performed and often promoted when alkalies are taken into the stomach in sufficient quantities to hold the reputed amount of acid in a neutral state.

371. On the contrary, digestion is always impaired by the introduc-

tion of acids into the stomach while the process is going on.

372. Did the supposed acid exist in the gastric juice, it would ren der the medicinal doses of the nitrate of silver, or the acetate of lead, perfectly inert. This principle is also of obvious application to many other substances. Indeed, it would be a perpetual "incompatible" with many remedial agents.

373. If digestion depend on the supposed chemical agencies, the stomach should always undergo more or less of that change after death; especially violent death. It is the rarest phenomenon, however, in man or animals, to witness the slightest change in that organ that

can be referable to the gastric juice (§ 366).

374. It is fundamental in nature that an organ which is designed for the production of an organic fluid does not also generate an inorganic substance, especially a simple element like chlorine, for the pur-

pose of bestowing organization and life.

375. Again, since it is the mucous tissue of the stomach alone which, in all animals, secretes a juice capable of producing chyme; and as no other part of any organized being can generate a substance of similar power, how arrogant, therefore, the supposition that art can manufacture a fluid of the same virtues (§ 323-325)!

376. As new aspirants enter the field, novelties, of course, will spring up. They serve, however, to show us the importance of regarding with suspicion whatever may conflict with the long-establish-

ed conclusions which have been drawn from an observation of the most common phenomena of living beings. This leads me to advert to the experimental researches of Dr. Schultz, the eminent Berlin professor, which, whatever be their foundation, effectually destroy our confidence in all those "digestive mixtures" which have figured, of late years, so conspicuously in nearly all the systematic works on physiology.

In the first place, Professor Schultz infers that neither the stomach nor the gastric juice have much agency in digestion, but that this great office is mostly performed by the saliva. This distinguished

observer also finds that,

1st. "The secretions of the stomach are always alkaline excepting during the process of digestion."

2d. "No food undergoes digestion without saliva."

3d. "The chyme is not produced by chemical action, but is an organic compound formed by a vital transformation of the food."

4th. "There is no such product as the supposed acid gastric juice;

only a sour chyme" (§ 364, HUNTER).

5th. "The acid found in the stomach is the result of a chemical decomposition of the food" (§ 364).—Schultz, de Aliment. Concoctione

Also, the Rejuvenescence of Man, &c. 1842.

Again, still more recently, M. Blondlot, under the guidance of "experimental philosophy,"* affirms that the saliva is of the nature of mucus, little else than the waste of organs (as Liebig regards the gastric juice, § 350), contributing nothing to digestion, and only useful as a shield to the mucous surface (Blondlot, Traité de Analitique de la

Digestion, p. 124, 126).

376½. It appears, therefore, that all the prevailing physical views of digestion, the chemical doctrines of secreted products, the healthy and morbid processes of living beings, the modus operandi of morbific and remedial agents, which completely shuts out the magnificent laws of sympathy, and the whole bathos of the humoral pathology, have been, in recent times, the work of the laboratory. Physiologists and therapeutists, the British especially, appear to have forgotten that it is their business to explore the facts and the laws of organic nature, and to have turned the whole matter over to the chemist (§ 349, d). They have surrendered this high calling to the laboratory, and have bowed in submission to whatever its acids and crucibles have pretended to reveal as to the processes and laws of living beings. A vast number have thus discarded their lofty pursuits, and have substituted for them a most unnatural dependence upon the laboratory of the chemist.

The chemist has seized the opportunity with avidity; since his employment with inorganic nature is mostly analytical, mostly exhausted, while that which relates to living beings supplies an unbounded field for the institution of great principles and laws, whether true or false, and for the highest renown in philosophy. It is not remarkable, therefore, considering the prizes are few, the competitors many, that the "race is to the swift, and the battle to the strong," that the ambitious chemist should abandon the mere work of analysis, and push his inquiries into that magnificent department of nature where the richest laurels may be gathered. Inorganic chemistry supplies no such opportunities. Its work is analytical, and its principles few and simple;

^{*} An artificial fistulous opening in a dog's stomach (§ 366).

and this, alone, is the legitimate object of organic chemistry. That object has been lately well expressed by Mr. Hoblyn, in his Manual of

Chemistry. Thus:

"The peculiar principles which exist in all organized beings are distinct from those which operate on inorganic matters, and may be denominated organic agents. Their mode of operation is mysterious. The object of organic chemistry is to investigate the chemical history of the products which occur in the vegetable and animal kingdoms, and

which are hence called organic substances."

I therefore say, let us look well to the doings of the chemist. Let us properly regard his tampering with so profound a subject as physiology, whether in its natural or morbid aspects. Let us scrutinize his facts when he assails the experience of all the renowned in medical science through all past time, and declares that experience worthless (§ 350, mottoes). Let us not, however, indignantly retaliate upon him his attempts to overthrow the great fabric of medicine, or his efforts to undervalue the labors and the doctrines of men who have toiled in the field of organic nature, and have immolated themselves in the chambers of the sick. Let us rather kindly advise the chemist to cultivate modesty, and tell him, frankly, that, to comprehend the laws and the processes of living beings, they must be perpetually the objects of profound study, both in the natural state of the being and in all the variations to which he is liable from the influences of morbific and remedial agents. Let us tell him that he has acted wisely in refraining from all such observations, and in making the laboratory the exclusive theatre of his experimental inquiries. Either science, analytical, and limited in principles and laws, as chemistry may be, is enough for the compass of an individual; and medicine transcends the powers of the most gigantic mind. The physician, therefore, if he aim at the highest practical usefulness, or at the science of medicine, will find only the leisure to acquire the outlines of chemistry, and it is equally certain that the chemist who aspires at a profound knowledge of that department must spend his days and his nights within the precincts of his work-shop.

And now let us remember, that there is not one name in all the annals of medicine which rests for its distinction on the physical and chemical doctrines of life. On the contrary, in every instance where attempts have been made to carry the science of chemistry into physiology, in all, and every such instance, the individuals who have been so employed have sunk rapidly into oblivion; unless here and there a name, like Fourcroy's and Liebig's, which is rescued by lofty genius, and by purely chemical labors in the inorganic kingdom.

376²/₄, a. Finally, I will not forego this opportunity of bringing to the support of opinions which I have hitherto advanced the following extract from Judge Story's late address before the Alumni of Harvard University. It will be seen that the views of this distinguished man are entirely coincident with those which I had expressed in a former work. (See Medical and Physiological Commentaries, vol. i., p. 331-333, 310, 307, 308, 327, 385-400; vol. ii., p. 666-677, 801-815, 12, 13, 203, 644, &c.)

"I have said," says this eminent jurist, "that the tendency in our day is to ultraism of all sorts. I am aware that this suggestion may appear to some minds of an easy good-nature, or indolent confidence,

to be over-wrought, or too highly colored. But unless we choose voluntarily to blind ourselves to what is passing before our eyes in the daily intercourse of life, it seems to me impossible not to feel that there is much which demands severe scrutiny, if not serious alarm. I meddle not here with the bold, and yet familiar speculations upon government and polity, upon the fundamental changes, and even abolition of constitutions, or upon the fluctuating innovations of ordinary legislation. These might, of themselves, furnish out exciting themes for public discussion, if this were a fit occasion to introduce them. I speak rather of the interests of letters-of the common cause of learning—of the deep and abiding principles of philosophy. Is it not painfully true that the spirit of the age has broken loose from the strong ties which have hitherto bound society together by the mutual cohesions and attractions of habits, manners, institutions, morals, and literature? It seems to me, that what is old is no longer a matter of reverence or affection. What is established, is not on that account esteemed positively correct, or even salutary or useful. What have hitherto been deemed fundamental truths in the wide range of human experience and moral reasoning, are no longer admitted as axioms or even as starting-points, but at most are propounded only as problems, worthy of solution. They are questioned and scrutinized, and required to be submitted to jealous proofs. They have not even conceded to them the ordinary prerogative of being presumed to be true until the contrary is clearly shown. In short, there seems to me, at least, to be abroad a general skepticism—a restless spirit of innovation and change—a fretful desire to provoke discussions of all sorts, under the pretext of free inquiry, or of comprehensive liberalism. And this movement is to be found not merely among illiterate and vain pretenders, but among minds of the highest order, which are capable of giving fearful impulses to public opinion. We seem to be borne on the tide of experiment with a rash and impetuous speed, confident that there is no risk in our course, and heedless that it may make shipwreck of our best hopes, and spread desolation and ruin on every side, as well on its ebb as its flow. The main ground, therefore, for apprehension, is not from undue reverence for antiquity, so much as it is from dreamy expectations of unbounded future intellectual progress; and, above all, from our gross over-valuation and inordinate exaggeration of the peculiar advantages and excellences of our own age over all others. This last is, so to say, our besetting sin; and we worship the idol, carved by the cunning of our own hands, with a fond and parental devotion. There are many even among the educated classes, and far more among the uneducated, who imagine that we see now, as men never saw before, in extent, as well as in clearness of vision; that we reason, as men never reasoned before; that we have reached depths and made discoveries, not merely in abstract and physical science, but in the ascertainment of the moral and intellectual powers of man, and the true structure and interests of government and society, which throw into comparative insignificance the attainments of past ages. We seem to ourselves to be emerging, as it were, from the darkness of by-gone centuries, whose glow-worm lights 'show the matin to be near, and 'gin to pale their ineffectual fires,' before our advancing radiance. We are almost ready to persuade ourselves that their experience is of little value to us; that the

change of circumstances is so great, that what was wisdom once is no longer such; that it served well enough for the day, but that it ought not now to be an object of desire, or even of commendation.

"Nay, the comparison is sometimes eagerly pressed of our achievements in literature with those of former ages. Our histories are said to be more philosophical, more searching, more exact, more elaborate than theirs. Our poetry is said to surpass theirs in brilliancy, imaginativeness, tenderness, elegance, and variety, and not to be behind theirs even in sublimity, or terrific grandeur. It is more thoughtful, more natural, more suggestive, more concentrative, and more thrilling than theirs. Our philosophy is not, like theirs, harsh or crabbed, or irregular; but wrought out in harmonious and well-defined proportions. Our metaphysical systems and mental speculations are (as we flatter ourselves) to endure forever, not merely as monuments of our faith, but of truth; while the old systems must fall into ruins, or merely furnish materials to reconstruct the new-as the temples of the gods of ancient Rome serve but to trick out or ornament the modern churches of the Eternal City. Ay, and it may be so. But who will pause and gaze on the latter, when his eyes can fasten on the gigantic forms of the Coliseum, or the Pantheon, or the Column of Tra-

jan, or the Arch of Constantine?

"May I not stop for a moment, and ask if there is not much delusion and error in this notion of our superiority over former ages; and if there be, whether it may not be fatal to our just progress in literature, as well as to the permanent interests of society? I would not ask those who entertain such opinions to accompany me back to the days of Aristotle and Cicero, whose works on the subject of government and politics alone have scarcely received any essential addition in principles or practical wisdom, down to this very hour. Who, of all the great names of the past, have possessed so profound an influence and so wide an authority for so long a period? If time be the arbiter of poetical excellence, whose fame is so secure as that of Homer and Virgil? Whose histories may hope to outlive those of Thucydides and Tacitus? But I would limit myself to a far narrower space, to the period of the two centuries which have elapsed since our ancestors emigrated to America. Survey the generations which have passed away, and let us ask ourselves what have been their literary labors and scientific attainments? What the productions of their genius and learning? What the amount which they have contributed to meliorate the condition of mankind—to lay deep and broad the foundations of Theology, and Jurisprudence, and Medicine—to establish and illustrate the principles of free governments and international law-and to instruct as well as amuse the leisure, and to refine the taste of social life? Unless I greatly mistake, a calm survey of this whole matter would convince every well-balanced mind, that if we may claim something for ourselves, we must yield much to the scholars of those days. We shall find that much of our own fruits have been grafted on the ancient stocks. That much of what we now admire is not destined for immortality. That much which we deem new is but an ill-disguised plunder from the old repositories. And that much which we vaunt to be true consists of old fallacies, often refuted and forgotten, or of unripe theories, which must perish by the wayside, or be choked by other weeds of a kindred growth.

"The truth is, that no single generation of men can accomplish much of itself or for itself which does not essentially rest upon what has been done before. Whatever may be the extent or variety of labors and attainments, much of them will fail to reach posterity, and much which reaches them will be felt, not as a distinct formation, but only as component ingredients of the general mass of knowledge. Many of the immortals of one age cease to be such in the next which succeeds it; and, at best, after a fitful season of renown, they quietly pass away, and sleep well in the common cemetery of the departed. What is present is apt to be dazzling and imposing, and to assume a vast importance over the distant and the obscure. The mind in its perspective becomes affected by the like laws as those of the natural vision. The shrub in the foreground overtops the oak, that has numbered its centuries. The hill under our eye locms higher than the snowy Alps,

which skirt the edge of the horizon.

"But let us subject this matter to a little closer scrutiny, and see if the annals of the last two centuries alone do not sufficiently admonish us of the mutability of human fame, as well as that of human pursuits. What a vast amount of intellectual power has been expended during that period, which is now dimly seen, or entirely forgotten! The very names of many authors have perished, and the titles of their works are to be gathered only from the dusty pages of some obscure catalogue. What reason can we have to suppose that much of our own labors will not share a kindred fate? But, turning to another and brighter part of the picture, where the mellowing hand of time has touched with its finest tints the varying figures. Who are there to be seen but Shakspeare, and Milton, and Bacon, and Locke, and Newton, and Cudworth, and Taylor, and Barrow, not to speak of a host of others, whose works ought to be profoundly studied, and should illustrate every library. I put it to ourselves to say, who are the men of this generation to be brought into comparison with these, in the extent and variety of their labors, the powers of their genius, or the depth of their researches? Who of ourselves can hope to exercise an influence over the human mind as wide-spread as theirs? Who can hope to do more for science, for philosophy, for literature, for theology, than they? I put the argument to our modesty, whether we can dispense with the products of their genius, and wisdom, and learning; or may cast aside their works, as mere play-things for idlers, or curiosities for collectors of the antique?

"I have but glanced at this subject. It would occupy a large discourse to unfold it in its various bearings and consequences. But the strong tendency of our times to disregard the lessons and the authority of the past must have any thing but a salutary effect upon all the complicated interests of literary as well as social life. It not only loosens and disjoints those institutions, which seem indispensable to our common happiness and security, but it puts afloat all those principles, which constitute, as it were, the very axioms of all sound philosophy and literature. In no country on earth is the danger of such a tendency so pregnant with fearful results, as in our own; for it nurses a spirit of innovation, and experiment, and oscillation, which leaves no resting-place for sober meditation or permanent progress. It was the striking remark of an acute observer of the human mind, that 'he who sets out with doubting, will find life finished, before he

becomes master of the rudiments;' and that he who begins by presuming on his own sense has ended his studies as soon as he has

commenced them."—Judge Story's Address, &c.*

3763, b. In parting, for the present, with organic chemistry would again pay my humble tribute to a science of exalted worth, in its vocation of laying open the constitution and laws of inorganic nature, and in applying its results to many of the most useful purposes of life. The physiologist venerates the science, does homage to its cultivators, would do battle for its cause. In protecting the great Institution which it is his province to illustrate, in preserving unsullied the stupendous philosophy of Medicine, he makes no encroachment on a sister science; but, ever obedient to the voice of Nature, he worships in all her temples (§ 1034).

4. DISTRIBUTION.

377. The fourth function common to animals and plants is distribution or circulation. In the former, after the food has become so far assimilated as to receive the final act of appropriation, or, in other words, after it is formed into blood, it must be distributed to all parts of the body, for their growth, nutrition, &c. This office is performed by the heart and blood-vessels in all perfect and superior animals, and by the blood-vessels alone in the inferior tribes, and whenever the heart is wanting. In the last instance the means are very similar

to those which carry on the circulation in plants.

378. The mechanism of circulation is shown by the function. In the perfect animals the blood is expelled by the left ventricle of the heart into the aorta, and thence distributed to all parts of the body; where it is applied to nutrition and secretion, and undergoes depuration by the excretory organs. Such as is not thus appropriated is sent forward to the communicating veins, by which it is conveyed to the right auricle, and from thence to the right ventricle, to be distributed to the lungs through the pulmonary artery, and returned, again, to the left ventricle through the pulmonary veins and left auricle. In the lungs, the venous blood is converted to arterial, and perfected for the various exigencies of organic life, by the joint agency of the pulmonary mucous tissue and atmospheric air (§ 419, 827 b).

379. A remarkable exception occurs to the foregoing general plan of the circulation in the transmission of venous blood from the abdominal viscera to the liver, through the vena portæ. It is also anomalous, that this blood is appropriated, in part, to the formation of an organic fluid, the bile, while the residue is transmitted to the vena cava through the hepatic veins; these veins being also the associate medium for the return of blood from the hepatic artery (§1031).

380. There are three principal distinctions between the blood sent out by the left ventricle and that which is returned to the right: 1st. The color of venous blood is a modena red; that of arterial a bright scarlet. 2d. Venous blood is more highly charged with carbonaceous matter than the arterial. 3d. Venous blood will not support the life of organs.

381. The blood supplies all parts with their means of nutrition, secretion, &c., and is, itself, the stimulus by which its own circulatory organs are excited to motion, and by which the formative and secretory vessels are maintained in their action. The pabulum vita is,

* See a remarkable parallel to the foregoing in TACITUS' Dialogue concerning Oratory. The coincidences should admonish us the more.

therefore, remarkably distinguished from all other substances in nature, in being equally the stimulus of the whole circulatory system, and the substance acted upon and appropriated according to the na-

ture of every part in which it may circulate (§ 136).

It is the same with the sap of plants as with the blood; both being alike the pabulum vitæ. Each is every where converted into the solid organs to which it is distributed, and into fluids and other products which have their special allotment in organic life; and nothing is formed which is not derived immediately from the blood or sap (§ 41-44, 847 c, 1053).

OF THE POWERS WHICH CIRCULATE THE BLOOD.*

382. Much of the philosophy of medicine is involved in a right estimate of the powers which carry on the circulation of the blood. But, having set forth this subject extensively in the Medical and Physiological Commentaries, I shall now limit my remarks to a state-

ment of the most prominent facts (§ 407, a).

383, a. A great error has prevailed of ascribing the circulation of the blood to the propelling power of the heart alone. Another, less common, imputes venous circulation to the action of the capillary arteries; while a still greater regards it as a hydrostatic phenomenon dependent on the arterial column of blood. Another, subversive of all principles in medicine, refers the circulation in the capillary vessels—those instruments of all the essential organic processes—to capillary attraction. Another supposes that the blood is moved in virtue of its own inherent power. Another, that the globular portion is composed of animalcula, which traverse the circulatory system by their locomotive endowment. But, the most obnaxious to objection is the latest speculation which flows from the universal doctrine of Liebig, that

"All vital activity arises from the mutual action of the oxygen of the atmosphere and the elements of the food;" that "the life of animals exhibits itself in the continual absorption of the oxygen of the air, and its combination with certain component parts of the animal body;" and that "the cause of the state of motion is to be found in a series of changes which the food undergoes in the organism; those changes being the results of processes of decomposition, to which the food itself, or the structures formed from it, or parts of organs, are

subjected." (See § 350, nos. 9, 10, § 1054).

This last hypothesis imputes the circulation entirely to the chemical action of oxygen gas upon the tissues and upon the blood itself; rejects, altogether, the propelling and suction power of the heart, overlooks the respiratory movements, the peristaltic action of the intestinal canal, the permanent contraction of the sphincters, the motions of the iris, denies all vascular action, even in the face of such phenomena as blushing, and all other sympathetic movements, nor recognizes a local morbid physiological determination of blood, or a morbid process, or a physiological influence of therapeutical agents, but construes all these unique results upon the same chemical phenomenon.

383, b. A modification, however, of this doctrine concedes an instrumentality of the heart in circulating the blood. The heart still acts in virtue of the combustive process; and so far the doctrine is

^{*} The term powers, as here employed, comprehends the instruments of circulation.

consistent. But it is fundamentally contradicted by the incongruity of the two great sources of power at the apex and at the circumference of the circulation, when contrasted with the exact balance which prevails between the moving power of the heart and the circulation of the blood in the capillary system. Non is there to be found in nature two such distinct sources of power for the accomplishment of a specific effect as that which imputes the circulation of the blood to an associate mechanical impulse by the heart and a chemical process in the capillary blood-vessels (§ 129).

384. There are numerous elements concerned in the circulation of the blood, each one of which I have endeavored to substantiate in a

former work.*—See also p. 934, § 1090.

1st. The heart possesses, through its vital properties, an active

power of dilating and contracting (§ 498, e, 1090),

2d. The arteries possess a similar power, though in a far inferior degree. This has been determined by the application of irritants.—
(Medical and Physiological Comm., vol. ii., p. 147-152, 375-403.)

3d. The capillary arteries, or the reservoirs of blood to the extreme vessels, have the same power, which is much more actively exercised than in the larger arteries. The capillaries are consequently brought into greater action when stimulated by physical agents, as in inflammatory diseases, or by the nervous power, as in blushing (§ 480, 1039), or as it lights up inflammation (§ 647½, 746 c, 973–974).

4th. The extreme vessels, or terminating series of the arterial system, have, also, a like power of contracting and dilating actively, and in a still greater degree than the capillary arteries (§ 136, 750).

5th. The extreme capillary veins have, also, a special action of the foregoing nature, which aids in transmitting the blood from the arte-

rial system to the next larger series of veins.

6th. The larger veins possess the power of dilating and contracting actively, according to the varying quantities of blood transmitted from the arterial system. Their constant *conatus* to contract on their contents assists in the transmission of the blood.

7th. All the cavities of the heart operate upon the principle of an

exhausting pump, during their dilatation.—Note BB p. 1131.

385. All the foregoing powers (§ 384) concur together, according to a consummate Design, in circulating the blood. All are important elements; no one adequate in itself, while each should be studied by itself, as well as in connection with the whole (§ 74, 80, 117, 137, 143, 155, 156, 169 f, 266, 303 $\frac{1}{4}$ a, 306, 310, 311, 387, 399, 409 f, 422, 514 h, 524 d, 525, 526 d, 528, 638, 733 b, 750, 764 b, 811, 847 c, 848, 902 f, 905, 1054). The Exp. &c. are in the Commentaries.*

386. The contraction and dilatation of the heart and arteries are, respectively, nearly synchronous. Although there be a perfect consent of action between the capillaries, the extreme vessels, and the heart, those vessels are not associated with the movements of the heart, nor with each other, in the same way as the actions of the heart and arteries; and they are modified, also, according to the special functions they perform in different parts (133 b, 135 a, 136). The case of blushing shows us the law in regard to the capillaries (§ 476, &c.).

387. The final cause of motion in the veins is chiefly that of sub-

^{*} Medical and Physiological Commentaries, vol. ii., p. 375-426, 147-152, and the Essay on the Theories of Inflammation, ibid.

serving the arterial system; and here the consent of action between the veins and arteries is still more illustrative of the profound nature of the principles and laws which govern the functions of organic life. It has been, indeed, the universal doctrine that the capacity of the veins is determined in a mechanical manner by the volume of blood transmitted from the arteries; but I have endeavored to show that the supposed physical distension and elastic contraction of the veins are without foundation, and would form a most serious obstacle to the circulation of the blood. On the contrary, it appears that those actions are not only of a vital nature, but that they are a perpetual illustration of sympathy, depending upon sympathetic relations of the veins to the communicating series of arterial capillaries.

This peculiar constitution of the veins explains the reason why they collapse when divided; since their sympathetic relation to the arteries is thus extinguished. The veins, indeed, appear to be not less susceptible of action from the stimulus of sympathy with the capillary arteries than the iris with the retina (§ 514, k), whose phenomena so clearly demonstrate the operation of that principle in developing sensible motions; but compounded as to veins of continuous and remote.*

The dilatations and contractions of the veins are, therefore, very greatly effected by reflex nervous influences exerted upon them by the varying states of the capillary arteries, as well as by the quantities of blood they are employed in transmitting to the veins. These influences appear to be originally felt by the capillary series of veins, where the organic properties are most strongly pronounced, and thence propagated by continuous sympathy to the larger series (§ 498, and Comm., vol. ii., p. 520, 521, &c.), when reflex actions ensue.**

Did not a consent of action with the arteries (depending on the principle of sympathy, § 452, 495, &c., 498) exist in the veins, the vital contractility, and the elastic property of the coats, must be mechanically overcome by the increased quantity of blood transmitted to them. The blood must be forcibly injected into the capillary veins by the vis a tergo, and in numerous parts of difficult penetration by the finest injections of art. This is utterly repugnant to that Unity of Design which prevails in all parts of the organized being, and would be leaving an important function to a fortuitous and inadequate provision. Nor can it be consistently supposed that the phenomena which appertain to one class of vessels are of a vital nature, and those of the other, resulting in an anatomically associated series, mechanical.

The veins possess, also, longitudinal fibres, by which they are fitted for rapid and uniform motion over an extensive tract; and this action implies a predominance of continuous sympathy (§ 498). It is also proved that the veins, like the heart and arteries, dilate actively on the application of certain stimuli to their external surface.—
(Med. and Physiolog. Comm., vol. ii., p. 147-152, 375-401.)

388. Venous circulation is determined principally by the suction or derivative power of the right cavities of the heart, but is aided by the contractile power of the large veins, by the more specific action of the capillary veins, and by the propelling power of the communicating series of arterial capillaries. The contraction of the left ventricle of the heart, and that of the large arteries, have little or no agency in venous circulation. Their force is probably exhausted, or

^{*} Continuous sympathy is continuous influence of these Institutes (sec. 129 c, f, 498 a)

nearly so, when the blood has reached the terminal series of the arte-

The blood is returned from the lungs to the left cavities of the heart

by the powers just stated.

It is not alone the dilatation of the auricles which constitutes the derivative power, as had been supposed till I investigated this subject;

but equally, also, that of the ventricles (§ 1090).
389. In the Medical and Physiological Commentaries, I have examined every objection which has been alleged against the imputed dependence of venous circulation upon the dilatation of the cavities of the heart, and atmospheric pressure. One objection had been stated with greater force and apparent plausibility than the rest, by Drs. Philip, Arnott, and other eminent men; namely, that the parietes of the veins should collapse upon the supposed doctrine of suction. To this objection I have replied, that the injecting power of the communicating arterial capillaries maintains the veins in a state of fullness. The perfectly harmonious relation among the powers which circulate the blood establishes a correspondence between the movements in the venous and arterial systems, by which nature has duly provided against so great an evil as apprehended.

390, a. The suction power of the heart, as I have endeavored to show in the "Commentaries," is indispensable to the portal circulation, and to that, also, of the lymphatics, lacteals, thoracic duct, and umbilical vein; though, doubtless, the independent action of these

vessels contributes to the motion of their contents.

390, b. In the foregoing work I have considered the objection relative to the occasional jet of blood from a vein wounded in venesection in certain conditions of disease; and I purpose now, from its ambiguous relation to my subject, adverting to the causes of the intermitting pulse that so often attends congested states of the liver. This phenomenon has been long observed; but no substantial cause has been assigned. It is due, I apprehend, to two influences, one of

which is sympathetic, the other more or less mechanical.

The sympathetic is readily appreciated; the mechanical, and most important, requires explanation. In my Essay on Inflammation, and in the present work, I have endeavored to show that the current of blood is accelerated in the vessels immediately concerned in that morbid process, notwithstanding the enlarged diameters of the vessels (§ 711, &c.). But not so in venous congestion, unless the propelling, and therefore, also, the suction power of the heart, be considerably increased. It often happens, however, that the force of the heart, in venous congestions of the liver, is even reduced below its ordinary standard, however there may be an attendant hardness of the pulse (§ 688). Now, therefore, since the veins undergo an enlargement in their congested states, and since, also, the volume of blood which is transmitted to the heart through the portal system is very large, if it enter that organ in an unusual manner, it is highly probable that it would embarrass its action. Such would be the effect of a sluggish or irregular ingress, especially, as will be seen, if not correspondent with the egress of blood.

But, it not unfrequently happens that the pulse becomes intermittent, for the first time, after the hepatic affection has sensibly yielded. This occurs, however, mostly, if not altogether, in rather intense forms of venous congestion, and where the force of the heart, and therefore its suction power, are manifestly increased, so much so, indeed, that practitioners, cautious of blood-letting, will venture upon the remedy. An incomplete subsidence of the disease, and the means of treatment, reduce the action of the heart; and the suction power being thus lessened, while the veins remain yet enlarged, the blood moves with a tardy pace in the portal veins, and disturbs the

rhythmic action of the heart.

There is also another, and important element of this mechanical cause, which consists in an interrupted balance between the blood which enters the heart and that which is projected from it; its entrance being rendered slow by the state of the portal veins, while its projection is unembarrassed. If the pulse be merely intermittent, and only so after several beats, excitement from exercise, but not from the mind, will often restore, for a short time, the harmony of both ventricles. Mental excitement, on the contrary, through nervous influence, is apt to increase the intermission, and often adds an irregularity (§ 227, 509, &c.). But, unlike the simply intermitting, an irregular pulse is commonly increased in its irregularity by violent exercise, as well as by excitements of mind. The intermitting pulse, on the contrary, is often most strongly pronounced in the horizontal posture. Reflex nervous influences enact a part in this phenomenon.

The nature of the *sympathetic* cause will be readily appreciated by the accurate observer, when he considers how often intermissions or irregularities of the pulse are increased by a full, and some-

times a scanty meal (§ 512), through reflex nervous actions.

Cerebral inflammation often gives rise to an irregular action of the heart; but here the cause is determined by the nervous power alone (§ 226, &c.). In the case of the brain, also, the pulse is apt to be more irregular than intermittent; while in that of the liver it may

be both (§ 687, &c.).

391. The valves of the veins have been universally supposed to contribute essentially to venous circulation, by supporting the column of blood. This, however, I have endeavored to show, is a mistaken opinion;* for they are always open when the current of blood is passing. Like the valves of the heart their great final cause is to prevent the reflux of blood when pressure operates, and to contribute to the like design of the frequent inosculation of the veins. The supposed co-operation of the voluntary muscles in venous circulation is also

merely accidental.

392, a. It appears, therefore, that the whole theory of the circulation is strictly relative to the properties of life. The pressure of the atmosphere, by which the blood is forced along the returning vessels, is entirely incidental; and, although the transit of blood from one part to another is merely mechanical, its motion originates entirely invital agencies. The facts, of which the foregoing conclusions are predicated, are very numerous, and contribute to some of the most important pathological and therapeutical principles. It may be useful to consider yet farther some of the most indisputable, and to regard them, at the same time, in their connection with the laws of which they are the foundation.

392, b. Although the vascular system contributes an important part

^{*} Medical and Physiological Commentaries, vol. ii., p. 412, 426.

toward the common circulation, the heart possesses within itself a general control over this great function of life. Had it been otherwise, "a thousand causes might intervene, over which the organ, so limited in influence, could have no control, to retard or divert the course of the blood; and which, by occasioning one short delay, might prevent its return forever." It is, therefore, not only the great motive source, through its contractile power, in the universal act of distribution, but, to effect a return of the venous blood, "it is made the centre of atmospheric pressure and gravity, and designates the stage in the circulation in which a deficiency of supply would be the last in being felt. Hence it appears that the functions of the heart are performed, and life preserved, notwithstanding long and copious discharges of blood, which, upon any other hypothesis, must have been fatal. For, according to these hypotheses, the heart, or at least the auricles, are placed at the end of projection. They mark the highest advance of the tide, and would first be abandoned by the retiring They would be drained by every profuse hemorrhage, and the heart would expend its energy in fruitless efforts to circulate a fluid that came not within its reach." Upon any other theory, how could what Armstrong calls "the beautiful balance between the right and left sides of the heart" be preserved? How, otherwise, would the circulation be restored in syncope? In respect, also, to the absorbent power, it is farther well said by Carson, that, "though we are not acquainted with any data from which the power of the heart can be calculated, there must exist, nevertheless, certain limits, within which it must reasonably be supposed to be confined. If we consider that the quantity of blood in circulation is nearly one fifth of the weight of the whole body; that this great mass is spread over an immense surface; that it is therefore subjected to great resistance from friction, especially in the small vessels where each globule is to be rolled over a fixed surface; that the currents, in consequence of anastomosing branches, are perpetually flowing in opposite directions, and that attraction must powerfully prevail between the blood and small vessels; when we consider the mass moved, the motion with which it is moved, and the resistance opposed, it is impossible to imagine that this labor could have been performed by the propelling power of the ventricle;" besides the obvious objections of the liability of the curvature of the aorta and the capillary arteries to be ruptured, and the exigencies of the portal, placental, and lymphatic circulation (§ 390).

Again, "the two trunks of the ascending and descending cava meet at the heart in such a manner as to form a straight line. The streams of blood which are conveyed by these vessels to the heart are placed at that point in direct opposition. Upon the supposition that the blood is returned to the heart by a vis a tergo, this position of the vessels is the most unfavorable that can be conceived for the office that is assigned to them. The momentum of blood in one vessel would be destroyed by that of the other; or, if the current in the descending was stronger than that in the ascending cava, the blood in the weaker

stream would be prevented from ever reaching the heart."

392, c. In the Medical and Physiological Commentaries, especially in the Essays on Inflammation, and the Powers which Circulate the Blood, I have exhibited a great amount of proof establishing the vital actions of the capillary blood-vessels, and showing that the mo

mentum of the blood, as derived from the left cardiac ventricle, is nearly lost in the capillaries. The opinion of Hunter, Bichat, Philip, and other distinguished observers, to the same effect, being founded upon the most ample investigations, would seem to leave no doubt upon a question of such fundamental importance in the philosophy of organic life. "Have they," says Wilson Philip, "who maintain that the circulation is supported by the muscular power of the heart alone, made even the rudest calculation of the degree of resistance to be overcome in driving the blood through two capillary systems at such a rate, that, in a given time, the same quantity shall be delivered by the veins, which is thrown into the arteries? Have they made any estimate of the strength necessary in the different sets of vessels, and particularly in the larger arteries, to sustain a power capable of overcoming this resistance? Let them give what imaginable power they will, they cannot make this power greater than the coats of the vessels will bear without rupture" (§ 1054, 1056).

So completely arrested, indeed, is the momentum of blood when it reaches the arterial capillaries, so manifest are the vital actions of these vessels, and so unaccountably did Philip and Bichat overlook the suction power of the heart, that they ascribed the circulation in the veins entirely to the propelling action of the capillary arteries. Owing to this limited view, Bichat was led to observe, that, "notwithstanding all that has been written as to the cause of venous circulation, there is an obscurity in it, in which there are but few rays of light." The circulation of the liver embarrassed him especially; since any general hypothesis which should fail here must be wholly abandoned (§ 390). He considered it, however, "incontestibly proved, that when the blood has arrived in the general capillary system, it is absolutely beyond the influence of the heart, and that the

left ventricle has no influence in the venous system."

392, d. The demonstrations of a direct nature, to show the independent action of the blood-vessels (the veins as well as arteries), are too numerous and various for concentrated observation. They are scattered throughout this work, and many of importance occur only in the Medical and Physiological Commentaries (vol. ii., p. 147-152, 375-401). The original suggestions of many belong to myself, as, also, their general application to the subjects before me. It has been one of my special objects to demonstrate an active dilatation of all the blood-vessels, as well as their active contraction. The latter, indeed, proves that the dilatation is active and vital. The greater principle lies in the necessity of a counteracting power; since active contraction alternating with dilatation necessarily implies corresponding principles of motion, or there would be a permanent state of contraction or tonic spasm. The sanguiferous system, therefore, would be devoid of function, and nothing but "stagnation" would be the great law of organic nature (§ 748, 1039, 1090).

393. The doctrine of venous circulation, as I have expounded it here, and proved it extensively in the "Commentaries," is replete with the most important physiological, pathological, and therapeutical conclusions. It strikes a fatal blow at the whole mechanical hypothesis and the stimulant treatment of venous congestion (§ 788-793), as shown in my Essay on that affection. It determines all the great fundamental points which have been in dispute respecting the circu-

lation of the blood. It proves that the propelling force of the left ventricle of the heart is lost, or nearly so, in the extreme capillary arteries. It proves, what is of greater importance than all things else in the Institutes of medicine, that the extreme vessels possess an independent vital action; since otherwise the blood could never be carried forward in the veins by the power of suction (§ 389). But that would not be the greatest oversight in the plan of organic nature (§ 1039, 1040).

394. The highest practical, as well as philosophical, conclusions are involved in a correct estimate of the powers which determine the circulation of the blood (§ 393). But there are no errors so prolific of evil, and so derogatory to medical philosophy, as that which assumes a passive state of the terminal series of the arteries, or that circulation is carried on in that series by capillary attraction, or by

their oxydation (§ 383).

Were either of these hypotheses true, there could be none of the organic products, as derived from the blood, no secretion, no nutrition—not a principle in physiology, pathology, or therapeutics; for all the essential organic functions, and all the processes of disease, are carried on by the terminal series of the arteries (§ 481 g, 483, &c.).

Consider the phenomena of sympathy; contemplate the experiments of Philip to determine the laws of the vital functions; study the laws of the nervous power in their relation to organic functions; observe how instantly mental emotions will variously affect the action of the heart, or bring a suffusion of blood to the pallid face, or how stimuli applied to the brain will as instantly produce corresponding results (§ 481-485); and you will concede that these results of the operation of the nervous power demonstrate the independent vital action of the capillary vessels, and overturn the physical and chemical hypotheses of life.

395. The foregoing influence of the cerebro-spinal and ganglionic systems upon the capillaries and extreme vessels is of the highest importance in pathology, and in the philosophy and treatment of disease. These vessels are not only the instruments of disease, but they sustain all the morbific influences which result in sympathetic diseases, and upon these vessels all remedial agents exert their curative effects, whether by their direct action, or through the instrumentality of the nervous power (§ 222-233, 456 a, 1039, Note BB p. 1131).

396. Nor is it alone an active condition by which the terminal series of arteries is remarkably distinguished. Our various facts establish the no less important principles, that the several orders of terminal vessels have their vital properties and actions strongly pronounced, and that these properties and actions are peculiarly modified in their natural state, both in a general sense, and in different parts, and that they are liable to various other peculiar modifications from the operation of morbific and therapeutical agents. Hence, all our curative means must have a steady and direct reference to the existing condition of these extreme capillary vessels (§ 149, 150, &c.).

397. Of the extreme vessels physiologists have supposed, with great reason, that there are at least three series; one being destined for nutrition, another for the secretion and excretion of the fluids, and au-

other series coinciding with the veins.

Without being disposed to submit this question, in the least, to the

microscope (§ 131), there might be allowed, according to Wagner, what has probably been hypothetically suggested by the well-known simplicity of nature, that there is "but one kind of termination in reference to an artery—a passage into a vein through a capillary vessel, and an intermediate net-work." In this case, however, there must either exist lateral projections from the terminal capillary, or there must radiate from the "intermediate net-work" vessels whose office is to distribute the blood from which are eliminated the materials for nutrition, &c.

398. The extreme vessels which are destined for nutrition, secretion, and excretion, elect from the blood, contained in their reservoirs the capillary arteries, the precise elements that are necessary to the formation of each peculiar compound throughout the body, and in such uniform proportions and modes of combination as shall forever, and without deviation, render them exactly conformable to the nature of every part, as ordained at the Creation (§ 41-44). This is done in virtue of the peculiarly modified states of irritability and other properties of life, according to the exact office of every part. Yet are these the vessels which are said to be under the sole government of physical and chemical laws (§ 383), and whose morbid state in inflammation is constituted by a mechanical relaxation of their parietes, and a stagnation and coagulation of their contents (§ 711, &c.)!

399. In their natural state, the foregoing vessels admit but very few of the red globules of blood, in virtue of their peculiarly modified irritability; and this, therefore, where the calibre surpasses the diameters of the red globules. There is no mechanical "straining off of the finer from the coarser parts of the blood" by an inadequate capacity of those vessels which convey only white blood (§ 493, d). The separation is effected in a homogeneous substance, and by causes which are very foreign to "strainers" and "sieves" (§ 129, 135-138, 266, 750). The same principle interprets the admission of the red globules into those serous vessels, in inflammation. Irritability is there morbidly affected, and the usual process of vital decomposition of the blood is, of course, arrested (§ 327-329). The entire blood then finds its way into the lymph vessels, as they are called; and the organic law by which that result is determined (§ 192, 278) is beautifully illustrated by two experiments; one by Buniva, the other by Procter The experiments also confirm the doctrines which I have taught as to the character of the nervous power, and its agency in organic actions, while both observers pursuing different routes, and attaining a common end through opposite effects, but by common principles relative to the nervous power, illustrate and confirm the experiments of each $(\S 222-233\frac{3}{4}, 476, \&c., 500).$

Buniva had great difficulty in effecting an injection of an artery of a living dog, till he divided the spinal cord, when, by thus withdrawing the stimulus of the nervous power, the capillaries lost their peculiar susceptibility, and the contents of the syringe passed freely on.—

Buniva (§ 1039, 1056).

In Procter's experiment, "a horse was killed by dividing the medulla, the bowels turned aside, and the branch of the sympathetic nerve, which joins the ischiadic, laid bare; also, one of the arteries of the leg. A wire applied to the positive pole of a galvanic battery, defended with sponge, was applied to the nerve, and the nega-

tive wire to the artery. The positive wire was then drawn slowly along the plates of a fifty-plate battery and the effect was certainly not only to reproduce the pulsation in the artery, but also clearly to excite circulation in the more minute vessels." A by-stander exclaimed, "See how that pipe beats when they put on those wires!"—PROCTER, on the Sympathetic Nerve. 1844.

To the foregoing may be added the experiment by Dr. Hall (§ 263), which, it will have been observed, is insuperably opposed to his conclusions as to the agency of the nervous system in producing organic actions, and as examined in my Essays on "Vitality," &c. (p. 42, note). See, also, Experiments by Kriemer, § 485, and Philip, § 483,

and Dr. Parry's case, § 487, gg.—Note Q p. 1122.

5. APPROPRIATION, OR NUTRITION AND SECRETION.

400. Appropriation, like assimilation, is a comprehensive, though less complex, function. It embraces what are commonly designated as two functions, namely, nutrition and secretion.

401, a. A common fluid being formed, and distributed to the several parts of the animal and vegetable, is then appropriated to their

several uses.

401, b. Animals are distinguished by an unceasing change of the materials of which they are composed. The actions of life disturb the composition of parts, which, being thus unsuited for the purposes of organization, and reduced to a fluid state, are returned to the general circulating mass of blood, where they either again undergo assimilation, or are eliminated and cast off by the excretory organs. To supply this waste is, in part, the office of appropriation, which furnishes new molecules from the blood, in exact conformity with the process of disintegration after growth is completed, but occurring in excess while nutrition is engaged in rearing up the fabric to a state of maturity. Appropriation is also the function through which those secreted fluids, which act as auxiliaries in the processes of life, are renewed in their original character.

402. Appropriation, therefore, whether it refer to the increase and renewal of the solid parts, or to the production of useful fluids, being equally a process of secretion, every organic product, vegetable or animal, is the result of secretion. But appropriation, as applied to the useful fluids that are formed from the blood or sap, is more commonly known as an act of secretion; and though the next function which will be considered, namely, excretion, is very analogous, yet the final causes of secretion and excretion being entirely different, it is

. proper that they should be arranged as distinct processes.

Since, however, nutrition, secretion, and excretion are very analogous processes, secretion is a good generic term for the whole. Each process consists of certain acts by which new formations are generated from the blood. All parts are first eliminated in a fluid state. Such as are destined for nutrition assume the condition of the solids which they supply as soon as eliminated: such as subserve the uses of fluids remain permanently fluid. It is evident, therefore, that appropriation, in a philosophical sense, is the highest act of assimilation, but may be very properly regarded as a function by itself.

403. Every part of the body possesses a secreting apparatus, since

every part appropriates the blood to itself (§ 398).

404. The organs which generate the permanent fluid products are very various, and more complex than such as carry on nutrition. The former are either glands or simple membranes, acting in their compound condition (§ 92). The immediate instruments consist of a sim ple series of extreme vessels which pervade every part, and which are every where so constituted, anatomically and vitally, that they elaborate from the common nutritive fluid such compounds as are exactly conformable to the nature of each part respectively (§ 41-44, 133, &c., 135 b, 188, &c., 205, &c., 233, 397, 398).

405. The variety of secreted products, solid and fluid, is greater, and the quantity more abundant in animals than in plants, and in pro-

portion, also, to the complexity of organization.

406. The following products of secretion which remain more or less fluid occur in the animal kingdom. The first six are common to

most animals: 1. Gastric juice. 2. Saliva. Concerned in digestion. 3. Pancreatic juice. 4. Bile. Of the serous tissues. " cellular tissue. articular tissues. 5. Serous fluids. chambers of the eye. capsule of the lens. labyrinth of the ear. Of the mucous tissue of the mouth. " nose. 66 " pharynx. " larynx and 6. Mucous fluids. 66 lungs. 66 66 stomach. intestines. urinary and genital organs. skin of aquatic animals. 7. Tears. Suet, and fat of cellular tissue. Marrow of bones.

Liquids in the cryptæ of the skin. 8. Fatty or oily liquids. Cerumen of the ear. Fatty fluid of prepuce. Many other oily products. Ink of the sepia. Liquids of insects. Virus of serpents, &c.

trachea.

Fluids of defense.

Galvanism of torpedo, &c. 10. Humors of the spider, and of other insects, from which their webs, cocoons, &c., are formed. Germinal fluid.

11. Fluids necessary to the preservation of the \{ species.

Product of vesiculæ seminales. Liquor of Cowper's glands. Liquids in the fætal membranes. The milk of mammifera.

The foregoing fluids are variable according to the nature of the animal, but always the same in each species, and analogous, respective-

ly, in all (§ 53, &c., 83).

407, a. In considering the mechanism and the function of appropriation, it devolves upon the Institutes of Medicine, as in all other anatomical and physiological inquiries, to apply the whole to the elucidation of the laws upon which the mechanism is founded, and under which the phenomena take place. It will still be my purpose, therefore, to interrogate the whole in their various relations, and to illustrate the philosophy of the whole by contrasting the defects of

spurious systems.

407, b. The exact anatomical condition of the instruments of nutrition and secretion, as well as the functions themselves, can never be brought within the cognizance of sense; nor would it be of any practical use to know them beyond what is revealed by the vital and physical results (§ 83, 131). By these facts we are enabled to institute many of the most important conclusions in physiology. By them, especially, we demonstrate the errors of the physical and chemical doctrines of capillary circulation, and of the chemical and mechanical hypotheses relative to secretion. By them, we show that all the products from the blood, as well as effusions of blood in the ordinary forms of capillary hemorrhage, find their way out of the vessels through some vital act, and that the physical doctrines of percolation, and endosmose and exosmose, have no foundation in organic nature (§ 131, 275).

407, c. It has been also seen by demonstrations in respect to the development of the ovum, that appropriation is conducted by the same powers throughout the life of the being that were brought into action by the stimulus of semen; and it may be now added that the coincidence is beautifully enforced by a progressive and uninterrupted march of that primary development, which was instituted in the ovum, after the beginning of independent life (§ 63-81, 153-159).

408. The mechanical doctrine of filtration, which supposes the incalculable variety of secreted products to exist already formed in the blood (§ 41), still disfigures the physiology of the schools, and forms a prominent characteristic in the prevailing pathology of inflammation. To the whole of this subject, as well as to the chemical hypotheses, I have given an extensive investigation in my Essays on the Humoral Pathology, on the Vital Powers, on the Theories of Inflammation, on Endosmose and Exosmose, and on Diabetes, as embraced in the Medical and Physiological Commentaries. Many remarkable assumptions, intended to sustain the physical rationale of vital processes, are there examined and refuted. But, the explosion of one error, it has been said, often prepares the way for another; as exemplified in the following quotation relative to the hypothesis of endosmose and exosmose:

"This permeability to gases," says Liebig, "is a mechanical property, common to all animal tissues; and it is found in the same degree in the living as in the dead tissue."—Liebig's Animal Chemistry.—

See, also, § 350, 1031 b.
409, a. When considering the subject of proteine in a former section (§ 18), I reserved for this place all that was not immediately relative to elementary composition. What was there set forth should be applied in connection with what I shall now advance in continuation

of the subject.

409, b. We have seen that, in opposition to the received doctrines as quoted from Liebig in section 18, there is nothing in the secreted products of animals, solid or fluid, that subsist on vegetable substances similar to the food, except in elementary composition, nor in the blood itself; while it is also affirmed by Liebig, that "analogy, that fertile source of error, has unfortunately led to the very unapt comparison of the vital functions of plants with those of animals." But the reader, who may have attended to the parallel columns, and the sections on the chemical hypotheses of disease and therapeutics, will be neither surprised at the inconsistencies now and formerly indicated as to the prerogative of the vegetable kingdom in doing the whole work of assimilation, and even trespassing upon that of appropriation, in behalf of the animal tribes, nor unprepared for a farther explosion of the doctrine by its principal author. Let us, therefore, hear the chemist yet farther in his contradiction of the great fundamental doctrine (§ 18). Thus:

"We must not forget," says Liebig, "that, in whatever light we may view the vital operations, the production of nervous matter from the blood presupposes a change in the composition and qualities of the constituents of blood. That such change occurs is as certain as that the existence of the nervous matter cannot be denied. In this sense, we must assume that from a compound of proteine may be formed a first, second, third, &c., product, before a certain number of its

elements can become constituents of the nervous matter."

Again, having in view another special point, we are told that

"This much, at least, is undeniable, that the herbs and roots consumed by the cow contain no butter; that in hay, or the other fodder of oxen, no beef suet exists; that no hog's lard can be found in the potato refuse given to swine; and that the food of geese or fowls contains no goose fat or capon fat;"—"that as yet no trace of starch or sugar has been detected in arterial blood, not even in animals which had been fed exclusively with those substances."—(See Comm.,

vol. i., p. 674-682.)

And what gives special plausibility to these speculations is the controversy which has taken place between "the Reformer" on one side, and Dumas and other French chemists, on the other, respecting the origin of fat; the former maintaining that it results from transformations of sugar, starch, and other "vegetable proximates," while the latter contend that not only this, but agree with Liebig that all the other unique products of herbivorous animals are formed without the aid of their complex assimilating organs,—that they are merely applied as generated by the plant. In this latter doctrine is also seen a striking display of the human mind to run into simple views of nature; overlooking all the complicated facts and the whole labyrinth of animal organization, and making the ultimate sustenance of animal life but one remove from the constituents of the atmosphere (§ 303½, 304, 305, 322).

And again, when chemical demonstrations cannot be resisted,

"We must admit," says Liebig, "as the most important result of the study of the composition of gelatinous tissue, and as a point undeniably established, that, although formed from compounds of proteins it no longer belongs to the series of the compounds of proteine. No substance ANALOGOUS to the tissues yielding gelatin is found in vegetables."

Nay, not even in the blood itself; though,

"It is conceivable that membranes and tissues which yield gelatin are formed from albumen by the addition of oxygen, of the elements of water, and those of ammonia, accompanied by a separation of sulphur and phosphorus. At all events, their composition is ENTIRELY DIFFERENT from that of the chief constituents of the blood." "But there is no doubt that these tissues are formed from the constituents

of the blood"! Q. E. D.—Liebig's Animal Chemistry.

It will be thus seen that the chemist is finally coerced to the admission that many of the most important organic compounds depend altogether upon the specific action of organs by which they are elaborated from the blood, and that he is even embarrassed with a "doubt" whether "these tissues are formed from the constituents of the blood." The admission is comprehensive. It betrays the factitious nature of the whole physical rationale. It proclaims that every secreted product is different from the common source of supply, and different in every part of the animal. Chyme differs from chyle, and blood from either. Each differs in every species of animal, from man down to the whiteblooded tribes; yet each, wherever existing, is forever the same in the same species. And so with plants, even with such as seek for ammonia and nitrates upon the dung-hill, or others that gather iodine from the deep (§ 289, 350, nos. 261, 77). Each product, therefore, is generated in its unique characteristics by agents and processes which are designed specifically for the formation of each. Nor would this be doubtful to any observer who may pass along the various gradations of the assimilating organs from their simple condition in plants to that complexity which demanded the superaddition of the nervous systems (§ 336, 356 a, 461, 478 b, $488\frac{1}{2}$, 493 cc, 500 nn, 893 a, c, $893\frac{1}{2}$).

If we take, now, the premises on which the chemist proceeds to the exact conclusions which he sets forth in his formulæ of organic compounds, those who have been inattentive to his method will be surprised at its destitution of all but vague conjecture, where organic compounds are concerned; and, for the unique nature of these compounds the reader must turn to what I have said on the subject of

Composition. The following is the great starting point:

"The organs are formed from the blood, and contain the elements of the blood. They become transformed into new compounds with the addition only of oxygen and water. Hence the relative proportion of carbon and nitrogen must be the same as in the blood.

"If, then, we subtract from the composition of blood the elements of the urine, then the remainder, deducting the oxygen and water which have been added, must give the composition of the bile.

"Or, if from the elements of the blood we subtract the elements of the bile, the remainder must give the composition of urate of ammonia, or of urea and carbonic acid"! Q. E. D.—Liebic's Animal Chem-

istry.—See Lehmann's opinion p. 780, § 1029, 1031 b.

Such, once more, is the basis of organic chemistry, with all the apparent precision of mathematics in its extraction of a cube root; yet never the same in its analysis of the elementary composition of the blood, avowing the homogeneous nature of that compound of 17 or

18 elements, and, finally, in the very midst of its mathematical accuracy, allowing that there is no one organic compound elaborated from the blood by the *living* similar to the results of artificial processes. This I have already abundantly shown, even in the present section, and in another relative to it (§ 18). The same evidence abounds in the parallel quotations (§ 350), and a glance at the "Animal Chemistry," or the "Organic," would supply other facts for my present purpose. Thus, in the following sentences enough is conceded to substantiate my position; and it is worth the specific remark that "we know with certainty" that albumen and fibrin have not the same composition.

"We must be careful not to deceive ourselves in our expectations of what chemical analysis can do. We know, with *certainty*, that the numbers representing the relative proportions of the organic elements are the same in *albumen* and *fibrin*, and hence we conclude that they

have the same composition."

"If we reflect, that from the albumen and fibrin of the body all the other tissues are derived, it is perfectly clear that this can only occur in two ways. Either certain elements have been added to, or removed from, their constituent parts," and so on.—Liebig's Animal

Chemistry.—Note N p. 1121.

409, c. If the viper be fed exclusively with any one substance, its peculiar poison will be generated; and so of the characteristic products of the civet, the cuttlefish, the skunk, the beaver, &c.; each, also, being always generated by one particular part. Here, then, are tests for an important and comprehensive philosophy. From these we may descend along a scale, where we shall find in some of the secreted products of every animal and plant certain prominent characteristics which declare that not only these, but the less striking, also, are as much dependent on special organization, and special powers and actions, as the poison of the viper, or the fætor of the skunk, or the civet, or the beaver, or the ink of the cuttlefish, &c. Will any thing in nature, excepting the mucous tissue of the stomach, produce a substance at all analogous to the gastric juice? Is there any thing analogous to semen in the blood? Can it be generated by any thing but the testis (\S 83, b)? Can it be surmised that it is at all the product of forces which govern the inanimate world? Consider the nature of granulations, so obvious to the eye, and yet so analogous to the products of nutrition. From whatever parts of the body they spring up, they have all, originally, the same appearance. The same in bone as in muscle. But, so various are the modifications of their vital constitution, that they ultimately elaborate substances exactly conformable to the nature of the tissues, respectively, by which the granulations were generated. We know that there must be specific powers to effect these results, and that in each tissue, and in the granulations thereof, the powers are modified; and we know, also, that the results defy all explanation by any chemical or mechanical laws.

409, d. Carry the same principle to morbid conditions. Is not the virus of hydrophobia generated exclusively by the salivary glands, and by those glands in a particular state of disease, and probably, also, by the canine and feline tribes alone? Does not every morbid product require a specific mode of disease? Is not this distinctly exemplified in scarlatina, measles, small-pox; and, therefore, equally true

in less striking cases? Equally as true of common pus as of the pus of variola? And here I would refer to what I have said, in my Essay on Inflammation, of the nature and formation of pus;* how its formation is indiscriminately imputed by the same philosophers to a spontaneous alteration of blood in the large vessels, to chemical actions in the small, and to the decomposition of dead animal matter; how its analysis has led different chemists to opposite conclusions both as to its nature and formation; and how it is affirmed by the chemist to be unchangeably the same, whether the product of an abscess, of a chancre, or of the variolous pustule. The confusion in these respects is very remarkable, showing the perfect inadequacy of the principles by which the explanation is attempted; while they, who believe that animated nature operates by other forces, see nothing but admirable simplicity, and a fountain of the highest practical

advantages to mankind (§ 653).

409, e. Again, do we not find remarkable relations between the structure of secreting organs and the matter secreted (§ 346)? Where organization is most complex, the secretions are most compounded, and, as the structure becomes more and more simple, so also do the corresponding secretions. And yet, in the most simple membranes, apparently of the same organization, the products, according to Cuvier and others, are almost as various as the different species of animals, consisting of fluids in some, and of air in others; yet always the same in each species. On the other hand, what complexity of organization in the liver of the higher animals; yet all is precise, harmonious, and adapted to specific ends. Those ends, and that complexity, are fatal to all the chemical and physical views of the functions of assimilation and appropriation. And yet is the secretion of bile, which, according to the chemists, is composed of forty different compounds, and these made up of four or five elements, compared to what is supposed to be a chemical evolution of carbon from the blood; and the liver is also said, by distinguished physiologists, to be merely a "strainer of bile." We are told that "physiologists have been induced to suppose that the structure of the kidney is such that it allows the urea to percolate through the fine vessels emptying into its pelvis, like the mechanical operation of sifting or filtering, but denies a passage to the other constituents of the arterial blood." But how "deny" them; why do they never escape; why do not the constituents of the bile come this way, and vice versa? Is it more difficult for one substance to "sift and filter" its "passage" through one set of vessels than the other? The iatro-mechanical, it is true, are comparatively few with the iatro-chemical philosophers. The latter have also greater zeal. They are more recently in a field full of seductive novelties, and other allurements, while pure chemistry can offer nothing but the details of analysis (§ 1032).

409, f. All the secreted fluids not only have an apparatus peculiar to each, whose complexity corresponds remarkably with the compound nature of their products, but they are all destined for important specific ends in the economy of living bodies; a final purpose of which chemistry and physics are wholly incapable. One would be perfectly unsuited to the office of another, and would be even destructive of life, in most of the cases, should one product interchange with

^{*} In Medical and Physiological Commentaries, vol. ii., p. 181-204.

another (§ 129, 135-137). The saliva, gastric and pancreatic juices are designed for digestion; the blood being thus an almost direct cause of its own reproduction (§ 323-325, 356 a). The bile subserves three specific purposes, which, when regarded in their connection, supply one of the most remarkable instances of Design. This fluid participates directly in the assimilation of food, is the important cause of peristaltic motion, and performs, lastly, that inferior office, which is often regarded as its only one, of contributing with the lungs, kidneys, and skin, as an emulgent of the blood, though in a different aspect from the organs of excretion (§ 415, 423). The products of the serous membranes are designed, for the most part, to facilitate organic and voluntary movements; mucus serves, like the cuticle, to protect its organ against offending causes, &c.; the "humors" of the eye, and of the internal ear, are media of communication between external obiects and the nerves of sensation; and they are wonderfully adapted to the laws which they are intended to subserve. The semen, milk, fat, animal heat, &c., are other remarkable examples of final causes which secretion is intended to fulfill. To these might be added many others, less important, but not less to our purpose; as the poison of snakes and of insects, the galvanism of aquatic animals, the ink of the sepia, the fluid from which the spider builds his house, and with which we cure intermittent fever, &c. And, when we regard, in connection, the bile, the gastric juice, semen, milk, &c .- all derived from the homogeneous blood,—and consider the uniformity of their respective composition in health, their changes according to the alterations of the vital properties in disease, and these changes corresponding with certain modifications of the vital phenomena, are we not moved with astonishment at the total difference in their nature? Is there any relief for our astonishment but in a firm reliance upon powers that are equally unique in their operation? Would not amazement otherwise increase, till it should prove that the human mind does not rightly interpret the laws of nature, and is unjust to its own endowments?

409, g. If we now survey the vegetable kingdom, we shall find all things constituted upon the same plan. The poppy, digitalis, croton, spurge,—every thing growing side by side in the same earth, the same air, and watered with the same fluid, have, each one, its unique and unvarying sap and secreted products; an infinite variety of precise combinations derived from about four simple elements (§ 41, 42). Again, also, not only different species of plants when flourishing in the same soil yield different products throughout, but the same species have produced, from the day of their creation, the same identical products, in all their parts, in every variety of soil and climate. And so of all animals, whatever the variety of food. In the vegetable kingdom, we are also amazed at the systematic Design manifested in the coincidences between the various elementary combinations and their virtues as vital stimuli, or as morbific or remedial agents, which obtain among numerous species of many genera of plants, and which are maintained in all the varieties of soil to which the plants may be subjected. But, while these analogies prevail among the medicinal properties of certain extensive groups of plants, the products of each species, and of the several parts of the same species, have certain peculiarities, and these, too, will depend, in many plants, upon the stage of their advancement toward the flowering season, while they are not influenced by soil, climate, &c. (§ 52, 155).

409, h. Apply what has now been said of the products from the sap of plants to the formation of blood alone, which is composed of about the same elements, and we see how vain the attempts to explain by chemical laws even the formation of chyle; its conversion even from a white to a deep red color, and yet that color changing to white again under the influence of slight disease; and, finally, the vitality with which the blood is endowed. And, notwithstanding the complexity of the human body, its endless variety of food, and its artificial combinations and changes, has not the chemist given us a standard of the composition of the chyle, the blood, the gastric juice, bile, saliva, milk, &c., by which their morbid changes are to be tested in all countries, at all seasons, at all ages of man and of the world? Has he not told us that all this is so uniform in the natural state of the animal, so unlike the results of chemical agencies, that when changes arise they are indicative of changes in health? And does he not offer to show, that this alteration of the blood and secretions is so uniform under the same circumstances of disordered health, that you may tell by it the nature of disease and the appropriate remedy $(\S 5, 5\frac{1}{2} a)$? Is not this the basis of practical humoralism? I grant the fact as to the relation of specific changes in the secretions, the blood, also, and specific modifications of action. But is not all this in absolute opposition to whatever is known of the capricious operation of chemical forces? And what shadow of proof is there, that these vital powers, which the chemist now and then invokes to his aid, are not entirely adequate to the physiological results that are ascribed to the forces of chemistry?

409, $\hbar h$. As to the hypothesis which supposes that galvanism is identical with the nervous influence, and the efficient power in the formation of animal products, it is fully contradicted by the many analogous compounds generated by plants. This subject will have been variously considered in other places (§ 70–80, 409 k, 493 cc, 893 a, &c.).

409, i. And now, turning again to the mere physical theorist, if there be any who cannot appreciate the objections which I have set forth to their peculiar views of secretion, let them appeal to their ordinary habits of observation, and look at the condition of the blood as reputedly laden with the various compounds which are supposed to be strained off from the great vital fluid. What an unphilosophical mixture! All the forty ingredients of the bile into which that homogeneous substance is separated by the various manipulations of the chemist,—all the variety into which the urine is resolved by the same ingenious devices,-mucus, saliva, gastric juice, albumen, gelatin, cerebral substance, fat, tears, sweat, milk, semen, the germinal fluid, &c.,-nay, more, all the peculiar compounds which go to the formation of the different parts of the body; and each one, and no other, strained off by that part alone which has been forever engaged in the individual office of eliminating one exact compound, or one special variety of compounds. Nor is this the end of the absurdities; for the same physical doctrine supposes that this principle is coextensive with the vegetable kingdom, and that every species of plant and animal embraces in its circulating fluid special varieties, which, in the aggregate, make up the many millions of specific and unvarying compounds of which the organic kingdoms are composed (§ 41). Nor is it a small part of the difficulties which surround the mechanical and chemical hypotheses of secretion, that all these millions of compounds

are liable to exact variations, according to morbid changes in the

parts by which they are elaborated.

409, j. Is the chemical hypothesis of catalysis better calculated than the mechanical to resolve the great problem which concerns the formation of the millions of unique products from one common fluid, and in conformity with the facts which have been hitherto stated? This doctrine is, doubtless, the most ingenious of any which has been advanced by chemistry; but it has little to sustain it even of the specious analogies supplied by inorganic processes. Indeed, so little is catalysis supported by the phenomena of inorganic nature, that its existence is denied by many able chemists. Thus:

"Liebig," says Mülder, "has been led to reject catalysis entirely, and to give a totally different explanation of facts. He has assumed, that chemical forces are in action in those substances which, according to the supposition of Berzelius, are capable of exciting action, though without taking part in that action; and he thinks that by such chemical action, another may be excited in other substances. He adopts the principle, indicated by La Place and Berthollet, that a molecule, being put in motion, can communicate its motion to others, if in contact with them. He applies this principle to yeast especially," &c.—Mulder's Chemistry of Vegetable and Animal Physiology.

In section $350\frac{3}{4}$, d, is a brief statement of the catalytic theory as advocated by Mülder; and in the Medical and Physiological Commentaries (vol. i., p. 55-78) I have considered specifically the obstacles to its application to organic processes, while it must encounter, also, all that I have here alleged against the mechanical and other physical doctrines. Nor is it the least objection to the whole chemical system of organic life, that the two principal leaders in organic chemistry "give a totally different explanation of facts," that make up the essential attributes of living beings. Mülder affirms that Liebig's theory is an "assumption," while Liebig "rejects entirely" the catalytic theory of Mülder. The medical reader will easily appreciate the worth of Liebig's "assumption," by referring to its attempted "explanation of facts" as revealed by disease. (See § 350, nos. 40, 41, 42, 44, 45, $350\frac{1}{4}$, and Lehmann on Chemical Equations, § 1029).

409, k. In respect to the supposed agency of galvanism in the formation of animal compounds through the medium of the nervous system, the doctrine is consistently applied to the modifications which arise from morbid processes; but we have just seen (§ 409 hh) that the fundamental hypothesis is contradicted by the close analogy between the products of plants and animals, and by the absence of the nervous system in the former, and therefore, a fortiori, galvanism has no connection with morbid products. Galvanism is also alike a stimulus to the secretory functions of plants and animals, which farther establishes its distinction from the nervous power (§ 113, 224, 226, 356 a, 399, 446 a, 461, 475\frac{1}{2}, 493 cc, 500 nn, 512, 893 a, c, 893\frac{1}{2}, 902).—Note Y.

410. We may therefore well conclude that there is nothing so important in the whole compass of physiology, and in the philosophy and practice of medicine, as a proper understanding of the vital constitution, in their properties and functions, of those extreme vessels by which nutrition and secretion are performed. Those are also the instruments of all morbid processes, and those by which all morbid products are elaborated from the blood. And since all healthy products are clearly the result of processes to which there is nothing analogous in the world of dead matter, how obviously must all the products of disease, all those of inflammatory conditions, which vary but little from the natural standard, be owing to the same vital processes of those formative and secretory vessels somewhat diverted from their natural states, and in which deviations disease must be allowed to con-

sist (§ 750, 1039, 1040, 1056).

411. Finally, the function of appropriation is that which evinces, more than any other, the existence of a vital principle. This principle, being admitted as the basis of that function, must be carried to every other process of living beings. It is by appropriation that the new elementary combinations, in their endless variety, are formed from the blood or sap. By nutrition, which begins at the earliest development of the embryo in the aspect of growth, under the government of a peculiar power, as admitted by all, the organic being is carried forward to full maturity, and maintained while life continues. At every stage of his existence, it is the same process as that which was started by the impression of the semen upon the germ; and, since no new results are brought forth, no new powers can be called into operation. The living semen is the first stimulus of the organic properties of the embryo, and in this respect it is analogous to those vital stimuli which forever after maintain the same powers in action, and by which the same nutrition, or the same elementary combinations, are effected at every subsequent stage of existence. By nutrition, through the operation of these vital properties, and according to specific plans instituted by the Creator, and to be forever perpetuated by the substituted energy of the vital principle, all those forms of organic beings, which pass by almost insensible gradations from the mushroom up to the gigantic tree, and from the microscopic animalcule to the majesty of man, are maintained in all their exact peculiarities, in all their analogies to each other, in all their vital and moral attributes. It is by nutrition, that is to say, by the specific modes in which some three or four principal elements are united together, and joined to pre-existing parts of the same nature (§ 41, 42), that each animal or plant, according to its species, acquires and maintains a specific configuration and organization, exhibiting vital results that are peculiar to each, producing specific germs that are developed in exact conformity with the nature of the parent, and each pursuing forever a certain path which was marked out for itself alone by the Hand which gave it existence. Such, and far more, is the wonderful power, a power substituted for the Creator Himself, which directs capillary circulation, and governs the process of nutrition in the development of the embryo, in the maturity of the being, and in the perpetuation of the species.

Briefly, then, the whole essential philosophy of organic life, all that is important, or useful, or dignified in medicine, is directly relative to the vital constitution, and the vital actions of the formative and secretory vessels. Here is the labyrinth of life, here of disease, here the ultimate aim of medical philosophy (§ 1040).—Note I p. 1118.

6. EXCRETION.

412. Excretion is the sixth grand function common to animals and vegetables. It is analogous to secretion, and is performed by analogous organization; though the differences in these respects are probably greater than between nutrition and secretion, in their ordinary acceptation (§ 402 404).

413. By excretion useless matter is elaborated from the blood and ejected from the body. The results of this function, therefore, are entirely different from those of secretion, which are destined for use-

ful purposes in the animal economy.

414. The terminal series of the arterial system, as with appropriation, are the immediate instruments of the function of excretion. But, like secretion, a compounded organization is necessary to excretion. In this respect there appears to be about the same anatomical variety allotted to secretion and excretion (§ 404). The same tissue, indeed, and even the same part, may perform both functions; as in the lungs, and in the uterus (§ 135).

Notwithstanding, however, these coincidences, the final causes of excretion and secretion are so very different (§ 413), the processes which give rise to such opposite results should be regarded as differ-

ent functions.

415. The difference between secretion and excretion, as denoted by their respective uses, is confirmed by the elementary constitution of the products of these functions; those of secretion being organic, those of excretion inorganic. There is also reason to believe that special elementary changes take place in the urine soon after its elimination from the blood.* Urea may be also artificially produced; and such is not improbably the fact when chemically obtained from blood, or even from the urine (§ 53, b, 1032 a, Lehmann).

416. The principal excreted substances are, 1st. Carbon; 2d. Sweat; 3d. Urine. The lungs, skin, and kidneys, are the organs by which they are elaborated. The lungs and skin exercise their function, principally, after nutrition and secretion have been performed, and are, therefore, mainly concerned in excreting the waste parts of the body; though this devolves also upon the kidneys, especially in dis-

ease.

417, a. No one of the foregoing products is of an organic nature; and the supposed triumph of the chemist in manufacturing urea is no more a proof of the dependence of organic compounds on chemical processes than any other transformation.† The sweat and the urine being liable to transformations as soon as elaborated (§ 415), and more especially as every chemical agent by which their analysis is attempted necessarily changes their composition, their actual condition at the moment of their production can never be known. Such, also, is true of the analysis of every organic compound. The very analysis supposes the generation of compounds or of elements in artificial modes; but the original compound being the product of the organic powers, the transformation of its elements, whether spontaneous or effected by the chemist, and through certain agencies, occurs in certain determinate modes, and according to the influences which had been impressed by the organs of life (§ 54, a). Besides, it is now fully admitted that many very uniform and remarkable formations out of organic compounds, and themselves, too, allied to organic substances, have no such natural existence; as hydrocyanic acid, narcotin, &c. (§ 42, 409). Even Magendie threw in the way of proximate analyses the conclusive fact that, "during the short transit from the vascular tubes to your receiver, the component elements of the blood are found to effect a new arrangement" (δ 1032 b, c).

^{*} See Medical and Physiological Commentaries, vol. i., p. 526, 585, 602, 675-679.
† Leimann says that—"We can hardly any longer enumerate urea among true organic substances."—1550.

417, b. When, therefore, I may speak of changes in the "component parts" of organic compounds, I refer either to such as may be wrought by organic processes, or by influences exerted by less obvious causes, as in the case of the bile (§ 316), or to those chemical transformations of a specific nature which depend upon chemical agencies (a).

418. Carbon is the greatest excrement of animals, and is evolved from plants. In the former it is effected by the mucous tissue of the lungs, and often by the skin (§ 135); in the latter by the leaves (§ 303!).

419, a. The excretion of carbon by the lungs is construed by the chemists according to their rules of interpreting other organic actions. But, as I have endeavored, in the "Commentaries," to establish the vital character of this phenomenon, I shall only now advert to its philosophy, and in connection with that which respects the production of animal and vegetable heat (§ 433, &c.). They are thus associated by myself out of regard to the confusion which has befallen them in the hands of the chemist. But, appealing to him who sees in organic nature its plainest contradistinctions from inorganic, I would, in this place, submit to his understanding whether it be not probable that the same philosophy attends the elaboration of carbon by the lungs and by the skin, and whether that function of the skin in many animals be not as much an organic process as the associate secretion of sweat?

419, b. But, if the foregoing analogies be not sufficiently conclusive, consider, next, the elaboration of that excrementitious matter, the urine; which all but the purely physical philosopher recognize as a vital process. And, again, shall it be admitted that, while nature has constituted the pulmonary mucous tissue, like that of the stomach, intestine, bladder, &c., upon her universal plan of organization, and endowed it with the vital function of generating mucus, she has departed from it in an isolated part of one and the same continuous tissue to introduce, along with the vital, a chemical function? It is the same argument as derived from the production of sweat, in its connection with carbonaceous matter; and here the analogy brings into cooperation every product of the living being, and establishes the whole

upon common principles (§ $447\frac{1}{2}c$, 1032b).

419, c. There remains, however, a demonstration from analogy which is perfectly irresistible. We have already seen how differently modified in their vital character are not only different tissues, and tissues of the same apparent organization, but even different parts of one and the same continuous tissue. We have seen this exemplified in a variety of aspects, and especially by the specific nature of the product of certain parts. We have seen, for example, that there is nothing in nature but that part of the gastro-intestinal mucous tissue which lines the stomach that will generate gastric juice, while, also, it produces mucus (§ 133-136). Now, carry this to another part of the same continuous tissue which lines the air-cells, and the inference is plain that if the gastric juice be elaborated by a vital process, so also is the carbonaceous matter. Nor can any objection be urged that other parts of the mucous system do not contribute to the function of decarbonization upon the ground that they are less delicate, and therefore less permeable to the air, than the mucous portion of the lungs, since, in some animals, that dense organ, the skin, performs the same office. Nor is there a better chance for the application of en

dosmose and exosmose, since atmospheric air is often in contact

with the mucous tissue of the stomach (δ 447 $\frac{1}{2}$ c).

420. Perspiration or sweat, which is sensible and insensible, being elaborated by an organ of highly complex organization, is clearly a product of organic actions; and since the skin of some inferior animals, like the mucous tissue of the lungs, eliminates both mucus and carbon, this coincidence of function in two very complex organs may be considered worthy of some regard in forming the logical induction to which the facts in the preceding section may seem entitled.

421. The excretion of urine is the next great source of depuration to the blood. Like the other products of excretion, it contributes to the process of assimilation by its depurating effects (§ 416). It is astonishing, too, with what rapidity many substances appear in the urine after their admission into the stomach; often not more than five or ten minutes intervening. This rapidity of excretion is particularly true

of all matter which is offensive to the organization.

422, a. There is a remarkable sympathy subsisting between the kidneys and skin, by which, as it were, they interchange functions with each other. We are all familiar with the fact that the urine is most abundant in cold weather, and the perspirable matter most deficient, and vice versa; and, as a general principle, when one excretion abounds, the other is lessened. This is true in disease as in health (§ 129, 1032 a). It depends upon reflex nervous actions.

422, b. For the fulfillment of their final cause the kidneys possess an exquisite susceptibility to the influence of the nervous power (§ 188, &c., 226, 528). Hence arises the rapid and profuse excretion of urine when fear and certain other emotions of the mind are in operation. The same affirmation, too, may be made of the skin, though perhaps less extensively. This, too, is the reason why fear are owing to the direct development and determination of the nervous power upon the organs, respectively. These phenomena, too, prove the great susceptibility of the skin and kidneys to the influence of the nervous power, and are a key to the whole philosophy of the interchanges of action between the skin and kidneys (§ 129, 230, 638½).

But there are, also, as may be inferred from the facts just stated, great sympathetic relations between the skin and kidneys and many other organs, though these relations are much more manifested by effects which arise sympathetically in the excretory organs than by the influences of these organs upon other parts. This is mostly seen in disease, and during the operation of remedial agents applied to the stomach. So great, indeed, is the snsceptibility of the skin and the kidneys, in their excretory function, to remedial agents, that a large variety have received the denomination of sudorifics, and another class, diuretics. But, owing to the special vital constitution of the skin and kidneys, by which they are rendered sensitive in their excretory function to a thousand slight influences, it is obvious that the foregoing denominations of remedies convey hypotheses that are unfounded, and of injurious tendencies. There are no better sudorifics than fear and hot water; no better diuretic than impending danger (§ 246, 500, 8923, 1040); all through direct or reflex nervous influence.

422, c. In respect to the foregoing principle as shown by diseased conditions the facts are not less familiar. In such cases, an organ

which is naturally designed for secretion may sometimes, by a morbid increase of its products, take on the relative function of excretion, and thus, both by morbific reflex nervous actions, and by copious elaborations from the blood, diminish or suspend the excretion of urine. In the cholera asphyxia this excretion would fail entirely, even when the profuse intestinal discharges were unattended by the usual perspiration. But, in the case of the intestinal affection, much was due to the morbific, vital influences; since we often see the urine increased by the active operation of cathartics.* Scarcely a morbid state disturbs the organs of digestion without diminishing or increasing the effete products of the kidneys and skin, especially of the for-The kidneys, however, being designed for the mere purmer organ. pose of depuration, do not hold a corresponding sway over the great organs of life, but mainly so as it respects their dependence upon those organs (§ 129); while a greater reciprocity of sympathy between the skin and the essential viscera of life, and a predominant sympathy between the skin and kidneys as organs of excretion, evince the wonderful nature of Design in its provisions and limitations, according to the final causes which directed the plan of organic life (§ 325).—Illustrated by heart in § 500 m, $687\frac{1}{2}$ -688, $694\frac{3}{4}$, 826 cc.

423. How vain the attempt to refer any of the foregoing processes and results to any of the forces or laws which rule in the inorganic world! The entire rationale rests upon the peculiar operations of the nervous power, and its laws of reflex action (§ 222, &c., 446, &c., 455 e, 500). A balance of actions and products is thus perpetually maintained, though, of course, with less uniformity and exactness in sickness than in health. But nature, ever provident, has so constituted the properties of life, that when one organ, whether excretory or secretory, becomes morbidly suspended in its function, the evil will be felt by other organs, by reflected nervous action; and they will thus take on, as it were, the work of that suspended organ. If the excretion of urine be wholly arrested, not only the skin, but many other parts, may join in the concerted action of relief. But, no other part will ever excrete urine, no more than the skin will secrete semen.† The absurdity of this prevailing doctrine is shown, at once, by the fact that urine would excoriate the eliminating vessels of every part excepting those of the kidney (§ 83 b, 133, &c.).

Organs of pure secretion, however, may take on, in consequence of the foregoing condition, the office of excretion; that is to say, they will elaborate, along with their natural fluids, the excrementitious matters, in certain *peculiar* combinations, which, in the healthy state

of the kidneys, would appear in the form of urine (§ 417).

424. The philosophy of all that I have now said in respect to the interchange of offices among the organs of secretion and excretion, and of the dependence of the several products upon special conditions of anatomical structure and modifications of the organic properties, is the same that is concerned in the process of lactation after parturition, however different the remote and final causes. The mammary glands sympathize with the new change in the uterine system, and produce a fluid which is totally different from the blood, although, like all other products, it is derived from that fluid. And, there

^{*} See my work on the Cholera Asphyxia of New York, 1832.
† See Medical and Physiological Commentaries, vol. i., p. 526, 588, 603, 608, 680.

would be just as much wisdom in supposing that the reflex nervous action of the womb upon the mammary glands, at this critical juncture, is a chemical phenomenon, as there is in referring the elaboration of milk to the capricious forces of chemistry, while its reputed filtration from the blood, by others, is equally refuted by the sympathetic nature of lactation in every species of mammifera (§ 1031, b).

425. The excretion of urine, more than the products of any other part, may be affected by the absorption of unnatural agents into the circulation. This is because many agents which will excite the action of the kidneys are not offensive to the lacteals nor to the system at large, and are therefore freely absorbed. Such are many saline and alkaline substances, and others, again, which are natural to the body, as aqueous fluids, &c. Those being either unnatural or redundant rouse the action of the kidneys, as the proper organs for their elaboration. The quantity of urine is thus increased; and, while the kidneys are thus stimulated they may be rendered the means of excreting other matters, though in a very different condition

from their existence in the blood (§ 408).

426. In morbid states of all the principal organs the urine is remarkably liable to change. This arises from various causes. If the stomach be the primary seat of disease, or, if its condition be disturbed by reflected nervous influences of other diseased organs, as is almost constantly the case, digestion is imperfectly performed, and the chyle, in consequence, becomes more or less unfitted for the purposes of nutrition and secretion. The kidneys, therefore, carry off more than their wonted quantity of excrementitious matter, while this matter appears under conditions more or less varied from the natural product (§ 425). The whole office of appropriation is, also, more or less impaired, which farther modifies the condition of the blood and the formative action of the kidneys; though a part of the office of excretion, under these circumstances, devolves upon the skin and lungs (§ 416). A third great cause of the variableness of the urine consists in unusual vital decomposition or wasting of the body, or of some of its parts, when it devolves upon the kidneys to co-operate, beyond their natural habit, with the lungs and skin, in removing the redundancy of waste materials. A fourth cause of the urinary changes, and an important one, lies in actual morbid states of the kidneys themselves. The kidneys, however, are not often the seat of morbid affections beyond those of a simple functional and transient nature, as induced by reflex nervous actions excited by the diseases of other parts; but to which influences the kidneys are extremely liable, and, therefore, to consequent modifications of the urinary product.
427. Briefly, then, every alteration of the natural action of the kid-

427. Briefly, then, every alteration of the natural action of the kidneys, whether primary or sympathetic, and every defect in assimilation and appropriation, is attended by some change in the urine; while an endless variety is imparted to it by the qualities and quantities of the ingesta. From this circumstance, which should have prompted other conclusions, has arisen the belief that the state of the urine supplies some of the most important signs of pathological conditions, not only of the kidneys themselves, but of remote organs with which they may sympathize. From Hippocrates to our day, elaborate disquisitions have appeared concerning the changes of the urine as indicative of particular forms of disease, of their special seats, of the dif-

ferent stages of their rise and decline, and of their degrees of severity and danger. The humoralists were apt to regard the unusual conditions of this product, and other "vitiated secretions," as the disease itself; and in this respect they are imitated by the humoralists of the nineteenth century. Chemistry has been also brought to bear upon the fluctuating states of the urine, and has increased the factitious importance of a symptom which is often as likely to denote some alimentary substance, or divers forms of disease, or imperfect digestion, or some remedial agent, as the source from which it emanates.

But, coming to the bed-side we find that all these critical observations are relics of the speculative ages of humoralism. Here, we find that all that is practically useful in relation to the urine is generally best ascertained by mere inspection; and upon this subject, we have all, and more than is desirable, from Hippocrates himself. Those philosophers, however, who are employed in interrogating disease by chemical analyses are not often or long in the chambers of the sick. They carry on the investigation of morbid processes in the laboratory of the chemist, and then and there fabricate the appropriate reagents $(\S 5\frac{1}{2}, a)$. He who studies organic nature according to the method of solidism and vitalism has neither the leisure for those most difficult, unattainable, and laborious analyses, nor would they have any influence upon his judgment as to the pathology or treatment of disease, in the midst of such a multitudinous variety as is presented by the vital phenomena of disease. Of one thing, also, we may rest assured, that nature has supplied all those ready means for interpreting disease that may be necessary for immediate action; nor can we often delay the treatment of acute disease for consultations with the laboratory. In respect to the blood, were it even practicable to learn from analysis its variable conditions in disease, it would reflect no light upon morbid states of the organs, since the qualities of that fluid vary with every varying change in the vital conditions of the solids, and therefore, too, would fail to indicate, in the least, the appropriate remedies. This is also true, in a general sense, of the urine and all other excretions, and secretions. The ready sight, their sensible properties, the vital phenomena, physical signs, experience, and general principles, must be our guide. These may be sometimes facilitated by extraordinary modes of observation, but which are always within the reach and clear understanding of every practitioner; such as the usual mode of examining the blood in inflammatory diseases, evaporating the urine in diabetes, &c. On the contrary, were the humoral doctrines correct the teaching and the practice of medicine should be restricted to chemists alone; since there is no branch of inquiry so difficult as organic analyses, while their uncertainty would soon imply that the vis medicatrix natura is the only ordination of nature for the maladies of the human race (\S 691, 1033 b).

428. The menstrual fluid is another and a fourth product of excretion; and, from its close resemblance to the blood, in the human species, it is one of the proofs that capillary hemorrhage is generally the result of a secretory process. In the higher orders of animals, even a clearer index of its origin is supplied by the intermixture of blood with the periodic secretion of mucus, which, in lower orders, occurs without blood. The menses, however, is a product sui generis, and is

specifically determined by the nature of the part (§ 135). Unlike the other products of excretion, it is not essential as an evacuation, though important to the function of generation. It is therefore peculiar, also, in exerting important vital influences upon the genera-

tive system.

429. At certain periods of the year the female genitals of all animals undergo changes, by which they are developed or prepared for generation; as, for instance, the ovaria of birds become enlarged, the vagina of rabbits and of other animals is tumefied with blood, increased in its vascular action, and pours out an unusual mucous or bloody fluid. It is only at these periods that they are susceptible of impregnation.

430. But woman is capable of impregnation at all times; and that this may happen, her organs must be often developed and prepared

for the purpose.

The philosophy of the whole of this preparation, however various in different species, and at whatever intervals of time, is the same in all. The several conditions depend upon changes in the yital states of the generative organs, by which the sexual desire is excited, and the germ rendered susceptible to the stimulus of the semen. This is the end and the aim of the whole.

431. It follows, therefore, that the periodical excretion of the menstrual fluid is only essential to the office of generation, and not to the whole system, excepting so far as this excretion is a healthy function; and the suspension of any function being a morbid condition, the whole system may sympathize with the uterus when the menstrual

discharge is suspended.

432. Hence it follows, as a practical result, that all our prescriptions for suspended menstruation must proceed upon the principle that this excretion is a vital, and not a mechanical result; and that its suppression is owing to some morbid state of the uterus, either direct, or sympathetic.

7. CALORIFICATION.

433. Calorification is the function by which plants and animals generate the heat which is peculiar to themselves. Chemistry, however, has enjoyed a more undisturbed exposition of the nature of this function than even that of digestion; nearly all but the most eminent physiologists, such as Hunter and Bichat, having acquiesced in the speculations and assumptions of chemists as setting forth the true phi-

losophy of animal, or, rather, organic heat (§ 333).

It is obvious, therefore, that few things in medical philosophy have greater demands upon the physiologist than a right interpretation of this great and wonderful function of organic life, that its philosophy may be carried to the illustration of other organic processes, that all may be seen as a system of consistent Designs, and that no foot-hold, in the way of analogy, shall remain to him who would substitute artificial devices for the institutions and laws of Nature. The times have, and always have had, a demand upon the physiologist for a critical exposure of this extensive vitiation of medical philosophy. They urge it upon him now more than at former periods. Nothing has been hitherto done but to express opinions; and we now witness, as a consequence, an almost universal substitution of the chemical and phys-

ical theories of life, disease, and therapeutics, for the promptings of the most obvious phenomena of Nature. Mankind, in masses, in the aspect of Nations, are carried away by the simplicity of the chemical dogmas, and by the confidence with which they are uttered. They have become incorporated in most of our works on Physiology, Medicine, Hygiene. Nor is this at all limited to the Medical Profession. It is coextensive with society. It is ingrafted upon popular works; carried into our colleges, academies, and even public schools. It has become a part of the general plan of elementary education; and it is now most extensively an object, through voluminous publications, to induce the whole race of mankind to regulate their food by chemical analysis. Banners, I had almost said, are every where paraded, bearing the inscription from Liebig's Animal Chemistry, that

"To determine what substances are capable of affording nourishment, it is only necessary to ascertain the composition of the food, and to compare it with the ingredients of the

BLOOD.''

434. At the very outset of our inquiry, we discern the speculative nature of the chemical philosophy from the vast difference in the several hypotheses which have been advanced with equal confidence, and which, for awhile, have been received with almost universal favor. The theory of Crawford, which is relative exclusively to the lungs, and to the difference in the capacity for heat of venous and arterial blood, will not soon lose its fascinating simplicity nor the plausibility of its pretensions. Its elegance will stand forever in forcible contrast with that deformity which is the idol of the present day. Genius and taste will never cease to do their mournful homage to one, while they turn from the other as from the distortions of a Pagan deity.

A third hypothesis may be stated as contributing to the improbabilities of the whole, and which has not yet been fully supplanted by the greater novelty. This is that which ascribes the evolution of organic heat to the passage of the common nutritive fluid to a solid state. It has, even more than Crawford's, the merit of philosophical simplicity, and of an apparent foundation in nature, but far less of the spice

of genius.

435, a. The first two of the foregoing hypotheses have, as one of their indispensable elements, the union of the oxygen of the air with the carbon of the blood, or with that of the body; though, as I have endeavored to show in the Medical and Physiological Commentaries, neither that act in respiration, nor the excretion of carbon, has any greater connection with the production of animal heat than it has with that of the gastric juice, or any other result of organic functions. The whole of that subject is investigated so extensively in the work just mentioned, and, I may say, the speculations and assumptions which have been subsequently put forth by Liebig and his school are, also, so fully considered in the same work, either as already extant, or as likely to ensue, that I shall now limit myself to a statement of the latest and most approved positions of chemistry, and to such remarks and prominent facts as may be necessary to complete the integrity of those fundamental principles which are the main objects of this work, and to show that nature operates in her several departments, respectively, by general and not by partial laws, and that a

stable and perfect foundation may be thus laid, as it exists in nature for the great superstructure of pathology and therapeutics (§ 2, 892)

435, b. The arguments and the facts which I have employed in the foregoing Essay on Animal Heat must have been oftener approved than avowed, since they have been freely adopted by some subsequent writers without indicating the source from whence they were derived (§ 906, g).—See Rights of Authors p. 919, no. 23.

435, c. I may be also permitted to make the following extract from the Preface to the third volume of the Medical and Physiological Commentaries, published four years subsequently to the first two vol-

umes. Thus:

"In respect to chemistry, the author may safely affirm that not a fact has been subsequently disclosed that reflects the smallest light upon physiology or pathology. The whole of that ground, wherever chemistry has obtruded itself upon the science of life and disease, is so amply explained in the former volumes of these Commentaries, that not a substantial fact, nor a vague conclusion, has been put forth by the school of Liebig, which is not there examined, anticipated, and answered, as something which had already an existence, or was likely to emerge from the speculative philosophy of the laboratory then

in almost universal vogue" (§ 1 b, 350¼, 820 c).*
436. What, therefore, I may now say in refutation of this or of other chemical doctrines of organic processes and results, will consist, in part, of a summary view of some of the facts and arguments which are arrayed in copious detail in the Medical and Physiological Commentaries. And, truth being my only object, I shall begin the subject under consideration with a statement of the opinions of some of the most accurate and distinguished observers, which correspond with my own. But to show, however, that nothing but opinions have been expressed even by those who have comprehended the subject, I shall quote from each author all that I have any knowledge of his having said upon the question at issue, with the exception of the little which occurs along with Hunter's observations upon the temperature of trees. I will add, also, in proof of the necessity of these inquiries, that no preceding attempt had been made to show the errors of the chemical doctrines of digestion, and that I have incorporated in my prefatory remarks to that investigation all that I could learn from the distinguished authors whom I have there summoned in behalf of philosophy.—See Rights of Authors p. 919, no. 22,

437, a. Let us, then, hear the great French physiologist. "The extrication of caloric," says Bichat, "is a phenomenon exactly analogous to those of which the general capillary system is the seat."-"The disengagement of caloric is always subordinate to the state of the vital forces."—"The state of respiration has no influence upon the actual heat of the body."-" When we place on one side all the phenomena of animal heat, and on the other the chemical hypothesis, it

^{*} That this opinion is not peculiar to myself appears from critical notices of the Commentaries. Thus, for example, it is said by the distinguished author of the "Climate of the United States and its Endemic Influences," that,

"It will be seen that Dr. PAINE, in fact, anticipates the whole chemical theory of Liebics, as set forth in his 'Animal Chemistry.' This he does not only in his Essay on Vitality, in which he controverts some of the German professor's opinions, advanced in the 'Organic Chemistry applied to Agriculture and Physiology,' but likewise in his Medical and Physiological Commentaries, published before the appearance of either of Liebic's works."

appears to me so inadequate to the explanation that I think every methodical mind can refute it without my assistance."—BICHAT'S General

Anatomy applied to Physiology and Medicine.

437, b. John Hunter, like Bichat, placed the elaboration of organic heat upon the same vital grounds; regarding it as a secreted product. "It is most probable," he says, "that the power of generating heat in animals arises from a principle so connected with life, that it can, and does, act independently of circulation, &c., and is that power which preserves and regulates the internal machine."—HUNTER'S Observations on Certain Parts of the Animal Economy.

437, c. And thus Wilson Philip: "Among the secretions I have ranked the evolution of caloric, although not taking place on any particular surface, because it appeared to be performed by the same power acting on the same fluid; and because, like secreted fluids, it fails when any considerable part of the influence of the brain or spinal cord is withdrawn."-PHILIP'S Experimental Inquiry into the Laws of the Vital Functions (§ 446, b).

437, d. And thus the philosophical Moore: "We must allow the bodies of living animals and vegetables to form an original source of heat, as much beyond our power of explaining as the source of the

sun's heat."—Moore's Medical Sketches.

437, e. And Müller thus: "From the experiments of Dulong and Despretz, it results that, even if the chemical theory of respiration be adopted, there must be still some other source of animal heat." "A general source of animal heat is undoubtedly to be found in the organic processes, in which, by the organizing forces on the organic matter, heat is generated not in one, but in every organ of the body." Again, "Since all organic processes are chiefly dependent on the influence exerted by the nerves on the organic matter of the body, it cannot appear wonderful if the reciprocal action between the organs and the nerves is a main source of animal heat."—MÜLLER'S Physiology.

437, f. Tiedemann has the same view of the subject. "The only point," he says, "that can be regarded as placed beyond doubt is, that the evolution of heat is a vital act which depends immediately on the process of nutrition, the conditional and preservative cause of life. The intensity of the evolution of heat, and the property of maintaining itself at a certain temperature proper to each species, are, in animals, in direct ratio with the composition of their organization, and with the sum and intensity of their manifestations of activity."—TIEDE-

MANN'S Physiology.

437, g. Finally, it is even said by the distinguished chemical physiologist, Dr. Carpenter, that, "It is evident that the chemical doctrine in its present form is insufficient to explain the phenomena of animal calorification."—CARPENTER'S Human Physiology, p. 611.

London, 1842.

438, a. The very able Dr. Edwards, in his work on the Influence of Physical Agents on Life, maintains that "respiration and animal heat stand related as cause and effect." This doctrine is maintained by Edwards with great ability; far more so than by all other authors whom I have consulted. I thought it, therefore, important to dispose of his facts and arguments, in my former work, as far as their plausibility and my own advantage of the right position would admit. There is much said, in the Commentaries, in refutation of that doctrine, which is at the foundation of Liebig's (§ 440), and to which

no farther reference will be made in this work (§ 1044).

438, b. Coming to the heterogeneous assumptions which distinguish the school of Liebig, there was no difficulty in anticipating the nature of such as might be relative to former theories. I had set forth the various doctrines in their ample dimensions, and brought them to the test of facts and philosophy. The combustion theory was then in vogue, and nearly in the terms as expounded by Liebig. In descanting upon its peculiarities I took for my guide the most recent and approved phraseology, which, it will be seen, is coincident with the supposed novelty; and, although it had numerous and ardent admirers, it passed into such oblivion, in the brief space of two years, that when Liebig promulgated the same hypothesis, and in the same language, it was hailed as one of the most brilliant achievements of that distinguished man (§ 349, d). The doctrine which had been thus nearly expressed by Billing, in his "Principles of Medicine," was taken for my text, and is now presented again, in its original typography. Thus:

"We have in the LUNGS a CHARCOAL FIRE constantly burning, and in the OTHER PARTS a WOOD FIRE, the one producing carbonic acid gas, the other carbon; the food supplying, through the circulation, the vegetable or animal fuel, from which the charcoal is prepared that is burned in the lungs. It is thus that animal heat is kept up."—BILLING,

1838 (§ $447\frac{1}{2}a$, no. 4, 1044).

438, c. Somewhat prior to Billing's day, Roget had embellished his "Bridgewater Treatise on Animal and Vegetable Physiology," by the following graphic description of the apparatus, and the office which each part fulfills in the generation of animal heat. Thus:

"The food supplies the fuel, which is prepared for use by the digestive organs, and conveyed by the pulmonary arteries to the place where it is to undergo combustion. The diaphragm is the bellows which feeds the furnace with air; and the trackea is the chimney through which the carbonic acid, which is the product of combustion, escapes."—Roger (§ 350\frac{3}{3}, f).

438, d. Now, the only fundamental difference between the foregoing and Liebig's hypothesis is this: The former supposes the combustion to take place in the lungs, the latter in every other part excepting the lungs, where, as will be seen, a special provision is made

for the temperature of those organs (§ $447\frac{1}{2}$, f).

That no imaginary obstacle may lie in the way of the vital theory, and that truth may have the advantage of rival doctrines by their close apposition, and that knowledge may not be limited to the facts and deductions of unadulterated science, it remains to show, by a series of quotations from Liebig's Animal Chemistry, that the doctrine of the dependence of organic heat upon the chemical process of combustion has gained nothing from the Laboratory at Geissen; while the attentive reader will find in the extracts themselves the most ample proof of its untenable nature. This, indeed, may have been well anticipated from what I have shown of this philosopher's regard for facts and consistency in section 350. Indeed, the same incongruities, the same contradictions, and worse assumptions, go to form the whole fabric of Liebig's disquisitions upon animal heat, as I have shown to make up his jumble respecting digestion, and other great functions, as well as properties of living beings (§ 1044).

I shall endeavor to execute my task with the same efficiency as was attempted in relation to the chemical views of digestion (§ 350), in the earnest hope that the chemist may discern the error of his ways, and leave to the student of Organic Nature those difficult problems which concern the highest welfare of man, and whose consistency, in their philosophical bearing, cannot be disturbed without laying in ruins every principle in physiology, and carrying death into the chambers of the sick (§ 4 a, 5, $5\frac{1}{2}$ a, $376\frac{1}{2}$, $376\frac{3}{4}$ b, 819, &c.)

440, a. Let us begin, then, with a statement of the doctrine as summarily delivered by Liebig in his work on Animal Chemistry, and we shall see from the first proposition that it is essentially the old speculation (§ 438, b), alike based upon artificial expedients, and upon the assumption that the living organism is a mere chemical apparatus, destitute of all properties and laws that are not common to dead

matter.

1. "It is evident that the supply of heat lost by cooling is effected by the mutual action of the elements of the food and the inspired oxygen, which combine together. The animal body acts, in this respect, as a furnace which we supply with fuel." "In order to keep up in the furnace a constant temperature, we must vary the supply of fuel according to the external temperature, that is, according to the supply of oxy-

gen."—Animal Chemistry.

It will be seen, from the close of the foregoing quotation, that a capital error is made in assuming a law that the quantity of food is regulated by the temperature of the air (§ 440 cc, no. 12). That assumption is carried out in opposition to all well-known facts; while it is also assumed as a law, that animal heat, whatever its uniformity in the warm-blooded animal, or its instability in the cold-blooded, depends upon the relative law of the temperature of the air and the quantity of food consumed, although this law is virtually contradicted by various other requisites for the promotion and maintenance of animal heat. But let us have another unqualified proposition which defines the law in relation to the dependence of animal heat upon external temperature and the food consumed. Thus:

2. "In different climates, the quantity of oxygen introduced into the system by respiration varies according to the temperature of the external air. The quantity of inspired oxygen increases with the loss of heat by external cooling, and the quantity of carbon or hydrogen necessary to combine with this oxygen must be increased in the same

ratio."—Animal Chemistry.

Now compare the following, 3, 4, and 5, with the preceding 1 and 2, and observe the conflict between them, and the contingencies upon which the great law is made to depend that determines a uniform

temperature. Thus:

3. "The quantity of oxygen consumed varies according to the temperature and density of the air, according to the degree of motion, labor, or exercise, to the amount and quality of the food, to the comparative warmth of the clothing, and also according to the time within which the food is taken"! A proposition mostly relative to man, and unfounded as to him (§ 440, c).

4. "The quantity of food is regulated by the number of respirations, by the temperature of the air, and by the amount of heat given off to

the surrounding medium"! (§ 447, c).

5. "The mutual action between the elements of the food and the cxy-gen conveyed by the circulation of the blood to every part of the body is the source of animal heat." "For a given amount of oxygen the heat produced is, in all cases, exactly the same."—Liebig's Animal Chemistry (§ 447, c, 1048).

6. "There is not the smallest support to the opinion that there exists, in the animal body, any other unknown source of heat, besides the mutual chemical action between the elements of the food and the

oxygen of the air."—Animal Chemistry.

No farther comment is necessary to indicate the complexities and contradictions involved in the foregoing quotations; such as "the quantity of oxygen consumed depends on the amount and quality of the food," while "the quantity of food is regulated by the number of respirations," that is, by "the quantity of oxygen consumed," &c.

If, also, we now add to the foregoing, 1, 2, 3, 4, 5, 6, other contingencies upon which it is assumed that animal heat depends, we shall have such a variety of accidental circumstances to interpret the uniform temperature of each individual of every species of animal, and that, too, according to the constitutional peculiarities of each species, that the nature of the chemical rationale will be sufficiently obvious. Thus:

7. "Where the food contains meat, fat, and wine, by reason of the hydrogen in those kinds of food which is oxydized, and which, in being converted into water, it evolves much more heat for equal weights."

8. "The cooling of the body, by whatever cause it may be produced, increases the amount of food necessary. The mere exposure to the cold air, &c., increases the loss of heat, and compels us to eat more than usual. [!] The same is true of those who are accustomed to drink large quantities of cold water. It increases the appetite, [!] and persons of a weak constitution find it necessary, by continued exercise, to supply to the system the oxygen required to restore the heat

abstracted by the cold water" !—Animal Chemistry.

440, b. Here I pause for a moment to advert to the ground of the assumptions in the quotations 7 and 8. The reason is one which goes conclusively to the vital theory of animal heat. When wine, for example, is taken into the stomach, an evolution of heat ensues as soon as the stimulant is swallowed, in virtue of its stimulant effect on that organ. In the same way meat stimulates more than vegetables, and will light up a glow upon a cold surface before its digestion has begun (§ 512, b). In respect to the superiority of cold water in provoking hunger, there is no other way of explaining the philosophy against the fact than by supposing "the Reformer" was pledged to the popular cause of temperance. But since wine, brandy, &c., far more than cold water, "increase the appetite" and "compel us to eat more than usual," and since these fluids are said to yield a far greater amount of "fuel" to the system than the food itself (whose main object is also supposed to supply the means of combustion), it should follow, upon our author's premises, that less food would be necessary to the purposes of life in proportion to the quantity of alcohol consumed, and therefore that wine should, in reality, diminish the appetite and "compel us to eat less than usual" (nos. 4, 7; § 441, e).

It may be worth observing, also, in respect to the "cold water," that the assumption is founded upon several important mistakes:

namely, 1st. That the appetite is virtually regulated by the condition of the calorific process; 2d. That "the animal body bears the same relation to surrounding objects (in respect to an interchange of calor. ic), as any other heated mass" (no. 14); and, 3d. That drinking cold water diminishes the temperature of the body (§ 442, b, c, d, e). And the most strenuous and extensive efforts have been made to choke down these absurdities under the penalty of being lampooned as an enemy to "experimental philosophy" ($\S 5\frac{1}{2}$, a). I have no doubt, however, that they will forcibly remind the reader of the parallel quotations, and of the pathological and therapeutical principles which emanate from them in the two subsequent sections.

440, bb. As to the "fat" (no. 7), the chemist assumed that to be an important source of animal heat because it is one of the best substances for combustion "in the air or in oxygen gas" (no. 10); and this hypothesis conducts him to the ludicrous mistake of regarding it equally, and in the same aspect, as a source of animal heat, whether it be taken as an article of food and converted into chyme, or consist of food which has been converted into the fat that makes up a part of the consumer. The uniform temperature, therefore, among a variety of other things, will depend not only on the amount of fat eaten, but on the amount formed out of the blood. This leads our author to

say that,

9. "If we were to go naked, like certain savage tribes, or if in hunting or fishing we were exposed to the same degree of cold as the Samoyedes, we should be able with ease to consume ten pounds of flesh, [!] and perhaps a dozen of tallow candles into the bargain, daily, as warmly-clad travelers have related with astonishment of these people. [!] We should then, also, be able to take the same quantity of brandy or train oil without bad effects, because the carbon and hydrogen of these substances would only suffice to keep up the equilibrium between the external temperature and that of our bodies."—Animal Chemistry (§ 1050). And yet Alcohol is not absorbed § 350, no. 94.

And that, too, in a critical work on science which professes a rigorous adherence to facts, as the only apology for a contemptuous derision of long-established doctrines, and as the only basis for the attempted substitutes. But let us now turn from "fat" as a combustible substance, via the digestive apparatus, to "fat" as appertaining to

the organized tissues (§ 1048, 1049).—Note N p. 1121.

10. "The formation of fat depends on a deficiency of oxygen. But, in this process, in the formation of fat itself, there is opened up a new source of animal heat. The oxygen set free in the formation of fat is given out in combination with carbon or hydrogen, and there must have been generated by the formation of carbonic acid or water as much heat as if an equal weight of carbon or hydrogen had been burned in air or in oxygen gas."-LIEBIG'S Organic Chemistry, &c.

Introductory to the foregoing quotation, we are told, that,

"The production of fat is always a consequence of a deficient supply of oxygen, for oxygen is absolutely indispensable for the dissipa-

tion of excess of carbon in the food."

And then we are referred, in illustration, to the "lean, muscular, inewy limbs that are exhibited with pride by the Bedouin and Arab of he desert" (c). But what says the variety in respect to fat, and oxygen nd heat, that prevails among the tenants of the ocean, who have but one common supply of food? Contrast, for example, the blubber of the whale, who breathes with lungs, with many a lean, voracious, cold-blooded animal that respires with gills. The hypothesis, therefore, falls (no. $11\frac{1}{2}$, and § 443, b). Or, if it survive such difficulties, take, then, the following statement, designed as an important basis for the combustion theory, and which should have had a place among our author's pathological doctrines (§ $350\frac{1}{2}$). But our present interest lies in the fact that it appears, after all, that it is not "true without exception," that "the production of fat is always in consequence of a deficient supply of oxygen." Thus:

"Exercise and labor cause a diminution in the quantity of the menstrual discharge; and when it is suppressed in consequence of disease, the vegetative life is manifested in a morbid production of fat"!

Here is another "most trustworthy observation," and "perfectly

conclusive" as to our author's doctrine. Thus:

"The quantities of oxygen which a whale and a carrier's horse can inspire in a given time are very unequal. The temperature, as well as the quantity of oxygen, is much greater in the horse."—Liebig's Animal Chemistry, &c.

Now the temperature of the whale in the frozen seas is more than 100° Fh., nor can the "carrier" bring up that of his horse to a higher degree, with the aid of a tropical sun. It is evident that our author

has regarded the whale as a cold-blooded fish.

440, c. I shall not now stop to inquire farther into the factitious nature of the foregoing doctrine, but go on with other extracts in which the author endeavors to sustain his great law of animal heat (5, 6), and expound by other contingencies that exact temperature which distinguishes every warm-blooded individual of every species of animal, and according to the nature of the species, and with scarce a variation, at all seasons, in all climates, at all ages, with all kinds and quantities of food, from him who "devours 10 lbs. of flesh and a dozen tallow candles into the bargain, daily, and the same quantity of brandy and train oil without bad effects" (no. 9), to him who, like "old Cornaro," lives on "half an egg a day;" and whether clad in the flannels and woolen broadcloths that are preferred as matters of comfort by many inhabitants of tropical climates, or absolutely naked, with Fahrenheit at 40° and lower, like the Petcherai Indians (442, b); or, whether sleeping or waking, sitting or standing, running or walking, in an ice-house or in an oven, in all past time, now, and forever; whatever statements our "Reformer" may make to the contrary notwithstanding. It will appear, therefore, that the following affirmations should be carefully considered, before they are admitted as appendages to the general law; namely,

11. "Our clothing is merely an equivalent for a certain amount of food, [!] The more warmly we are clothed the less urgent becomes the appetite for food, [!] because the loss of heat by cooling, and consequently the amount of heat to be supplied by the food, is diminish-

ed" (no. 9, and 12, and § 442 a, c, 1047, 1048, 1049).

Here our author predicates two important errors of the hypothesis which they are intended to sustain; the assumptions and the hypothesis

esis being mutually designed to support each other.

11½. But again; having seen that (in the language of Mr. Ancell, "the Reformer's" interpreter) "the deposition of fat is supposed to

act as a substitute for free respiration in the production of heat" (no. 10), we shall not be surprised to learn that "its absorption answers as a substitute for food in the production of animal heat." So it is ex-

tensively affirmed in the work on Animal Chemistry.

Why, then, is the temperature of a very fat ox and a very lean one, or of a very fat man and a very lean one, exactly the same in each species, respectively? Why does the fat man sustain a much less exaltation of heat than the lean one when emaciation is in rapid progress in febrile diseases? Why those daily periodical evolutions of heat $(100^{\circ}$ to 110° Fh.) in the emaciated subject of phthisis, subsisting on barley-water; and respiring with lungs unfitted for half their usual functions? And this leads me to state the chemical philosophy of mania and delirium, which flows immediately from the subject before us; and by which we learn, also, what is more important, the extent of our author's theory of combustion. Thus:

"In the progress of starvation it is not only the fat which disappears, but also, by degrees, all such of the solids as are capable of being dissolved. In the wasted body of those who have suffered starvation the muscles are shrunk and unnaturally soft, and have lost their contractility. All those parts of the body which were capable of entering into a state of motion have served to protect the remainder of the frame from the destructive influence of the atmosphere. [!] Toward the end, the particles of the brain begin to undergo the process of oxydation, and delirium, mania, and death, close the scene."

This construction of the cause of delirium and mania is conformable to the author's hypothesis of thought, mental emotions, &c. (§ 349, e); but that the phenomena are due to totally different influences "in the progress of starvation" is shown by the uniform preservation of the intellectual powers in the most emaciated subjects of phthisis pulmo-

nalis (§ 441, c).—See INDEX II, Article Hunger.

440, cc. But, we are only beginning with the contingencies which contribute to the fundamental principle of animal heat, and which are designed to interpret its remarkable uniformity, yet variety, in different species of the warm-blooded tribes, and its variableness in the cold-blooded, and to bring the general doctrine into correspondence with a great law of caloric which prevails in the inorganic world (§ 440 e, no. 14).

12. "In cold and temperate climates, the air which incessantly strives to consume the body [!] urges man to laborious efforts in order to furnish the means of resistance to its action, while, in hot climates, the necessity of labor to provide food is far less urgent"

(§ 445, b).—Animal Chemistry.

In the first place, all animals are overlooked in the foregoing statement, and our philosopher is actually regarding man as the only living creature who has a temperature above the surrounding atmosphere; for it surely will not be said of animals that they must work harder for a supply of food in temperate than in warmer climates. Nor will the reader fail to observe that much of the statements and reasoning, throughout, is predicated specifically of man, and of man, too, in a state of health.

As to the necessity of more "laborious efforts to provide food" in cold than in hot climates, a very different philosophy lies at its bottom than assigned by Liebig, which consists in the greater necessity of

labor to cultivate the earth and raise the means of supply in the for mer than the latter sections of the globe. It is evident, also, that "the Reformer" had not only man exclusively in view, but in that part of the contrast which relates to "hot climates," he was thinking alone of the indolent and luxurious master, without reference to the slave, who toils the day long under a torrid sun for his own scanty subsistence and his master's too.—Note Oo p. 1141.

But again, although man be compelled to work in cold climates "to provide food" to keep up his temperature, while this "necessity for labor is far less urgent in hot climates," the cold-blooded finny tribe, and the warm-blooded whale, and beasts of prey are quite on

an equality, in that respect, in all regions of the earth.

440, d. But, we are yet far from the end of the "contingent influences" which modify the exact law of animal heat (nos. 5, 6), and which go to the preservation of its exact uniformity. One of our author's hypotheses, which will be soon stated (no. 14), betrays him into a mistake, which has been often made and as often exposed. Thus:

13. "The contraction of muscles produces heat; but the force necessary for the contraction has manifested itself through the organs of motion, in which it has been excited by chemical changes. The ultimate cause of the heat produced is, therefore, to be found in these

chemical changes."—Animal Chemistry.

Now, setting aside the sophistry of this reasoning in a circle, we have the simple proposition that "the contraction of muscle: produces heat;" and evidently because "a piece of caoutchouc, when rapidly drawn out, forcibly contracts again, with disengagement of heat. And to this conclusion the "Reformer" was impelled by his fundamental doctrine that the living and the dead are undistinguishably governed by the same properties and laws, as implied by no. 14, and as extensively set forth in § 350. This assumption as to the effects of muscular motion I have sufficiently noticed in my former Essay on Animal Heat; but it may be now said that it is disproved by the uniformity of animal heat in all warm-blooded vertebrata, under all circumstances of rest and exercise. When the latter is sufficient to give an impulse to the general circulatory and other organs, an increased evolution of animal heat is liable to happen, like an increased flow of saliva, sweat, or any other secreted product; but it does not happen with any certainty, and is never due to the physical causes assigned; neither the mechanical one of "muscular contraction," nor the "chemical changes."

440, e. I come now to one of our philosopher's parallelisms of organic and inorganic beings in respect to their great laws and functions, and which necessarily flows from the grand physical hypothesis that

the living body is a mere chemical apparatus. Thus:

14. "The animal body is a heated mass, which bears the same relation to surrounding objects as any other heated mass. It receives heat when the surrounding objects are hotter, it loses heat when they are colder than itself."—Animal Chemistry. (See § $350\frac{2}{3}$, e, 1044 a, b).

Thus we have throughout a consecutive series of mistakes and blunders, emanating from a false position in respect to the fundamental constitution of living beings; while this perversion of nature is the monomania of materialism. But there remains much of the like na-

ture yet in prospect.

From the last proposition, and from the common level in which living and dead objects are regarded, and in his unacquaintance with physiological facts, the chemist has been betrayed into the supposition that all the contingent circumstances which I have now stated (nos. 1-14) contribute, along with the fundamental law, 5 and 6, to the production and maintenance of that uniform temperature by which every warm-blooded vertebrata is distinguished, while every other product of the tissues is forever variable in quantity, and which are to explain equally, also, the vicissitudes of the cold-blooded race, and all the

diversities of temperature which spring from disease.

The plainest facts in "experimental philosophy" contradict the as sumption, and place the generation of animal heat upon its own independent ground. If we enter an apartment heated to 260° F., the temperature of the body remains unaffected; and equally so in a bath of water, where all evaporation is prevented. If we pass the day in an ice-house, or dwell in an atmosphere at 50° below the zero of Fahrenheit, it is all the same (§ 442, c, d). If water, at zero, be dashed on the body, a glowing heat is instantly lighted up on the surface; and so it is upon the cold and shriveled skin of the starving man as soon as food shall have entered his stomach. A flash of indignation, or an impulse of shame, will, on the instant, set the whole face in a state of "combustion;" the face being then said, by common consent, to "burn" (§ 441, c).

With the last proposition (14) goes another which has the concur-

rence of all; namely,

15. "The heat given off to the surrounding medium is restored within the body with great rapidity."—"All living creatures, whose existence depends on the absorption of oxygen, possess within themselves a source of heat independent of surrounding objects."

16. And (for the third time, 5 and 6), "This disengagement of heat is, uniformly and under all circumstances, the result of the combination of a combustible substance with oxygen."—Animal Chem-

istry.

Such a chemical machine, with an internal source of heat, and con stantly liable to elevations and depressions of temperature from "surrounding objects like any other heated mass," could possess no stability of temperature,-none comparable with the inanimate objects by which its own internal source of heat is said to be influenced; and when we superadd the various other contingencies, the varying quantities and qualities of food, variableness of respiration, the oxygen respired, clothing, climate, season, weather, rest or exercise, age, fat, candles, train oil, and rum, which are said to have important influences on animal heat (nos. 1-14), and then carry out the assumed relation of the living body to "surrounding objects," and thus identify it with a "heated mass" of iron, a thousand other modifying contingencies present themselves, which, in connection with the "internal independent source of heat," should render the temperature of the living warm-blooded vertebrata variable at every moment, while that of the cold-blooded animal should be distinguished by the greater uni-

It need scarcely be added, that the warm-blooded vertebrata are remarkably exempt from the law which chemistry, to be consistent, imputes to them as conductors of caloric (no. 14). And herein, as

every where else, chemistry betrays the fallacy of its fundamental assumption (nos. 5, 6, 16). The warm-blooded vertebrata are especially contradistinguished from "other heated masses, in their relation to surrounding objects," by their resistance of heat from external objects (§ 441 c, 442 e); and this contradistinction is not only shown by universal experience, but forcibly so by the comparative relation which cold-blooded animals and "other heated masses bear to surrounding objects." These animals depend mostly for their temperature upon that of the surrounding medium, and consequently sustain much of the relation of "other heated masses." Still, they possess not only a feeble power of generating heat, but, what is more to my purpose, they have a corresponding power of resisting its ingress from surrounding objects, since it was ascertained by Crawford that "a living frog acquires heat more slowly than a dead onc."-London Philosoph. Trans., 1781, p. 485.

It is also worthy of remark, that the chemist has mistaken the rise of animal heat, when occasioned by the heat of a fire, for that interchange of caloric which takes place between inanimate substances of different temperatures. The phenomenon is peculiarly a fact for the vitalist, since, in the former case the rise of heat is due to the action

of caloric as a stimulant to the organic functions (§ $188\frac{1}{2}$).

On the other hand, when the temperature falls from the direct action of cold upon the living body, it is from the abduction of heat from the superficial capillaries alone, by which the calorific function is arrested not only in the skin, but may be, by reflex nervous action, throughout the body. And what also forcibly shows the vital nature of this phenomenon is the frequent and speedy exaltation of the cutaneous heat after its sudden reduction by the application of cold water (§ 1044).

440, f. In the midst of so much error and confusion, it is no difficult matter, as already seen (§ 350), to paralyze an author by an exposure of palpable contradictions in fundamental doctrines. example of this nature in relation to the present subject I shall place

in opposition the following statements:

Affirmative.

Negative.

17. "In whatever way carbon of combination cannot take place without the disengagement of heat. constant quantity."

been assumed that it is especially

440, g. These contradictory doctrines were put forth in different works, but almost simultaneously, and each was designed to sustain important hypotheses that regarded, respectively, the negative and the affirmative statement. But, even in the work on Animal Chemistry, a subject collateral to the general hypothesis of animal heat leads the author to a partial contradiction of his all-pervading idea of the ready combustion of carbon at temperatures as low, at least, as those of cold-blooded animals; since, upon that collateral subject, he says, "at the temperature of the (warm-blooded) body, the affinity of hydrogen for oxygen far surpasses that of carbon for the same ele-

(See § 441, e.)

440, h. I shall not undertake to decide whether oxygen unites singly with carbon or hydrogen, in the living body, or along with other elements from which the carbon is ultimately excreted, nor is it the province of these Institutes to inquire into a truth which belongs to the laboratory. In my former Essay on Animal Heat, I have examined this subject in its physiological aspect adversely to the chemical doctrine, and in conformity with the great law which excludes the formation of all inorganic compounds within the living organism, as set forth by chemistry (§ 38, 39, 419).

440, i. Of the remaining subsidiary causes, that relative to the bile should not be neglected. It is thus summarily expressed by Liebig's

interpreter, Mr. Ancell:

19. "These facts, and the reasoning founded upon them, have led Liebig to the conclusion that the function of the bile is to support respiration and produce animal heat, by presenting carbon and hydrogen in a very soluble form to the oxygen of acterial blood."—Mr. Ancell, in London Lancet, 1843.

The reader will, therefore, the more readily comprehend the doctrine of "the Reformer" as stated in the following language. Thus:

"In the carnivora the bile contains the carbon of the metamorphosed tissues. This carbon disappears in the animal body, and the bile likewise disappears in the vital process. Its carbon and hydrogen are given out through the skin and lungs as carbonic acid and water; and hence it is obvious that the elements of the bile serve for respiration and for the production of animal heat."—Animal Chemistry.

That may answer for the "carnivora;" while the graminivora depend more upon their "fat," and other tribes upon their special al-

Having already adverted to the true uses of the bile (§ 314-316

409 f), I shall proceed to say, without stopping to inquire how the foregoing "facts" were ascertained, that this part of the doctrine will hardly abide the test of morbid conditions. It often happens, for instance, when the production of bile is nearly or wholly arrested, that the temperature of the body is exalted above its natural standard, while at other times, when the bile is redundant, the temperature sinks below its equilibrium. This, too, is familiar to physicians as occurring in the progress of the same disease; and I have thus introduced this subject more for its bearing upon physiology and disease, than on account of its perversion by the chemist (§ 1031 b).

441, a. Having now set forth the principal doctrine, and the most important contingencies which are brought to its support, I shall proceed to make some farther comments both upon the doctrine and its auxiliaries, and present a variety of facts in confirmation of the phys-

tological theory of animal heat.

441, b. In the first place, it is worthy of farther remark in regard to a principal element of the main hypothesis, that scarcely any two individuals, of whatever species, consume the same quantities of food in a given time, while society abounds with habitual examples, where, under the same circumstances of age, health, sex, climate, temperature, employment, &c., there is every gradation in quantity from a daily consumption of many pounds to a few ounces, or with slight variations as to quantity in many individuals. Without, however, now reverting to the preceding relative statements of our author, let us adduce another for the sake of its logic and precision. Thus:

"The consumption of oxygen in equal times may be expressed by the number of respirations. It is clear that in the same individual the quantity of nourishment required must vary with the force and num-

ber of the respirations."—Animal Chemistry.

Immediately after this quotation, which has for its object an adjustment of "the quantity of nourishment required" for the assumed amount of carbonic acid generated in the body, we are told that,

"A child, in whom the organs of respiration are naturally very ac-

tive, requires food oftener than an adult."

Thus, therefore, according to this statement (which has the merit of being true, not only as it respects a "child," but all young animals), the author has presented a fact subversive of his hypothesis relative to the source of animal heat; since, if a "child" and all young animals consume more food and oxygen in the ratio of their size than men and adult animals, the power of evolving heat should be greater in the young than in the adult. But the experiments of Edwards, and others, have demonstrated that young warm-blooded animals may be cooled down rapidly to near the temperature of the surrounding air, which is impracticable with adults. But Edwards adds the fact, which farther confirms the vital doctrine of the generation of animal heat, that "the rapid progress which they make in acquiring the power of producing heat is wonderful." The same facts are applicable to a "child," though probably less so than to unfledged birds, puppies, &c. (§ 153-155, 442 a, 445 f). I may finally add, that the whole of this subject is extensively considered in my former Essay on Animal Heat.

441, c. Nor can I neglect referring the reader to the facts which I have arrayed in the Commentaries upon the subject of food, with a view as well to the humoral pathology as to the chemical doctrine of

animal heat,-how the northern savages, as known by observation. and from the necessity of the case, consume much less food than the civilized man of the temperate and even equatorial climates; the former, also, often breaking his fast only at distant intervals. There,* too, may be found a multitude of corresponding facts in relation to the endurance of Fasting without any sensible influence on the human system,—a general survey, also, of the habits of animals in relation to temperature, and which, like many of my arguments and other facts, have been advantageously employed by subsequent writers to accomplish what I had already done. I have urged the fact, in respect to animals, that they enjoy, ex necessitate rei, but a scanty supply of food in the arctic regions, and that, when gorged with the same sustenance on their removal to warmer climates, they still maintain nearly their original constitutional temperature; and there may be found a series of facts as to the relative temperature of the warm-blooded and the cold-blooded tenants of the deep, which, side by side in the arctic seas, subsist on food of the same quality; the whale, with a temperature of 102° F., and the far more voracious shark, whose heat is down to a lower standard. There it is urged, that when the emaciated hibernating animal is roused by pricking, &c., ay, even by exposure to a still lower temperature, 25° F., his heat suddenly rises from 39° to 97° F.; besides a multitude of similar proofs which should be examined in connection with what I have said extensively on the influence of the nervous system upon the generation of organic heat in the warm-blooded vertebrata (§ 1047, 1050).

How poorly accords our author's assumption as to the greater voracity of polar animals with the well-known facts relative to the hyenas, tigers, lions, crocodiles, vultures, cormorants, &c., that range in temperate and equatorial quarters! And what answer will chemistry make to the poor ability of all tropical animals to bear even the autumnal cold of the temperate zones, whatever the quantity of food?

But the facts are "the things," and let us, therefore, have them $(\S 5_1, a)$. They will show how far "the animal body bears the same relation to surrounding objects as any other heated mass" ($\S 440 e$, no. 14), and how far a large supply of food is necessary to the same animal temperature in frozen regions as appertains to the inhabitants of warmer climates.

In the Commentaries, then, I have called to witness, against the assumptions which I am again employed in refuting, the half-starved bears, and foxes, and reindeers, and hares, and even small birds, subsisting on a scanty amount of half-frozen food, and respiring and surrounded by an atmosphere at 30° to 50° below the zero of Fahrenheit; yet maintaining about the same temperature as when transported to a southern climate. I have said that "in 15 out of 16 foxes, the temperature was 100° to $106\frac{3}{4}^\circ$, in the other 98° ; the thermometer ranging below zero from 3° to 32° Fh. Capt. Lyon found that the tetro albus maintained its temperature at 50° below zero. It was, also, equally so with the smallest birds" (§ $442 \ b$, $446 \ d$, 1046-1050).

After what has been stated, however, of "tallow candles," "laborious efforts," "heated masses," "clothing," &c. (§ 440, nos. 9, 11, 12), the reader will not be surprised at our author's statement that, "every

^{*} Medical and Physiological Commentaries, vol i., p. 691-695. Also, the Essay on Animal Heat, in vol. ii.—1840.

one knows that the animals of prey in the arctic regions far exceed in voracity those of the torrid zone." And yet "every one knows" that the consumption of food is universally greatest where it is most abundant, and therefore least where it is assumed to be most abundant.

And what will the disciples of chemistry say to the fact that the low-born of the North of Europe, the exiles of Siberia, &c., often get little more than bread made from the wood of trees, and a wardrobe equally expressive of their destitution of the "comforts of life" (§ 442 b, and Commentaries, vol. i., p. 691-698)? What is the contrast in temperature between the well-fed loungers of Europe and the halfstarved laborers of the same countries ? What, again, between the slave and his master? One, too, feasting on animal food and other highly "combustible matter," in the shape of brandy, porter, wine, &c., while the other gets nothing but potatoes, yams, or bread, at best, and limpid water (nos. 7, 8)? Their temperature is alike. The only contrast in the case is between truth and error. Is the balance, then, to be found in the difference of clothing (no. 11)? Exactly otherwise; for the man of ease is incased with flannels and broadcloths, and lives in heated apartments (no. 14), while he of the shovel or the hod is no less contented and comfortable in rags, and whether he repose upon a bed of straw or a bank of snow. And here I may add, what is equally fatal to the chemical hypothesis, that this houseless sans culottes will maintain his warmth better with water than with rum, and that, the more he consumes of the "combustible substance," the greater will be his danger from frost (nos. 7, 9, Note Oo p. 1141).

It is also manifest that the ever-varying quantities and qualities of food employed by man in temperate and torrid zones, while his heat is always nearly the same, shows, with my other facts, that it is less dependent on food than are other products of organization. More especially is this demonstrated in many acute diseases, where the temperature of the body, or of particular parts only, is often greatly exalted, and where, too, the patient is wholly deprived of food, and emaciation so far advanced that not only the "fat," but the very "tis-

sues" are nearly "consumed."

Without inquiring into the hypothesis that meat is more combustible, and yields a greater quantity of heat than vegetable matter, it is important to place their relations to the calorific function in the proper

physiological aspect.

There is no doubt that the generation of heat is more promoted by animal than by vegetable food, until the system is accommodated to the latter by its habitual use; and even then the preponderance will be in favor of the former in high northern latitudes. The principle to which I now advert depends upon the law of vital habit and that which relates to the virtues of different natural stimuli, and is as foreign from chemistry as any two subjects can be from each other (§ 136, 150-152, 188½, 442, 512 b, 535-568).

The whole philosophy, then, which concerns the greater tendency of animal than of vegetable food to promote the generation of heat, consists in the fact that animal is a greater stimulus than vegetable matter to the organic functions (§ 188½, 512 b). The fact is demonstrable, as I have said, while the food lies yet undigested upon the stomach of the famished wayfarer; and every one knows that his warmth will be thus instantly increased to a greater degree by cold

meat than by cold potatoes (§ 512, b). And so is it, to a greater extent, with the alcoholic liquors which the chemist assumes are burned in the recesses of the organization (nos. 7, 9).* The principle which concerns the whole is exactly the same as when warm water lights up a glow upon the surface, or determines perspiration, or an act of vomiting. Here, too, in all this development of heat, as in the other results, is involved a magnificent agency of the nervous system, but which to the chemist is impenetrable darkness (§ 350, no. 97, 500 nn, 512 b).—See a curious contradiction about Alcohol, p. 172, nos. 43, 94.

Those that have but imperfect views in physiology may comprehend the merits of this subject by considering the relative effects of animal and vegetable food in fevers and inflammations. An ounce of the mildest broth may raise the temperature many degrees, while a liberal supply of appropriate vegetable food would have no such influence; though a great exaltation of temperature would ensue upon solid vegetable food that should not undergo digestion. The reason of all this gives the right interpretation to the relative effects of animal and vegetable food in the generation of heat in ordinary states of the system, or till habit may interpose its influence. Irritability being in an exalted state in febrile affections is more than usually susceptible of the stimulus of animal food, and hence the increase of vascular action and the greater evolution of heat, both from the direct effect of the food and the exciting reflex nervous actions it occasions.

Where vegetable food remains undigested, in the foregoing case, it becomes a morbid irritant to the stomach, and the cause of reflex nervous influences that augment the fever or the inflammation, and thus engenders a rise of temperature (§ 137 d, 150-152, 222, &c., 512, &c.).

The same philosophy is applicable to differences in climate. Little vegetable food is consumed in the arctic regions, and, as little animal food should be eaten by man in the equatorial. Nature has ordained this allotment to men and animals, by a scanty vegetation at the north, while she appears to have limited her provision of animal food in tropical climates to the wants of the carnivorous race. To the north she has given beasts and birds, but with a stinted hand, and has been scarcely more liberal of the tenants of the deep. To the tropics a profusion of esculent roots, fruits, &c.; and has displayed a munificence in animal and vegetable creation throughout the vast temperate regions. This ordination of nature is particularly suited to the exigencies of the human constitution. Animal food is especially stimulating to all the functions of man, and therefore to that which generates heat. Irritability is greater, more susceptible to the action of stimuli, in equatorial than in other climates. The tropical heat is its measure of endurance; and when the stimulus of animal food is superadded, the tropical man is extremely prone to fever, and dies early. If wine, brandy, &c., be added also, so much the worse; but not because it is "burned" in the body (§ 188, &c., 615, &c., 618). Our author's philosophy, however, is too much of a curiosity to be neglected, and should have gone along with the pathological inductions (§ 3501). Thus:

"The Englishman in Jamaica sees with regret the disappearance of his appetite, previously a source of frequently-recurring enjoyment; and he succeeds, by the use of Cayenne pepper and the most powerful stimulants, in enabling himself to take as much food as he

^{*} Alcohol appears to be in certain degrees digested, and in that state of transformation it undergoes absorption.—Note N p. 1121.

was accustomed to eat at home. But the whole of the carbon thus introduced into the system is not consumed. The temperature of the air is too high, and the oppressive heat does not allow him to increase the number of respirations by active exercise, and thus to proportion the waste to the amount of food taken. Disease of some

kind, THEREFORE, ensues."—Animal Chemistry.

Again, also, for a like physiological reason that animal food is too stimulating for man in tropical climates, vegetable is not sufficiently so for the obtuse irritability of the northern man (§ 191, 585, &c.); and it is therefore true in this acceptation that the arctic man would be more likely to freeze upon vegetable than animal food, despite of the superabundance of carbon in the former (§ 447, h). But, as I have said, and shown, he may, by the mere force of habit, come to endure the cold nearly as well upon vegetable as on animal diet

(§ 442 b, 535, 1048).

I will also say, that it is a vulgar prejudice that "train oil and talow candles" are appropriate food for man in any climate (\S 440 b, no. 9). The arctic, like every other man, would soon perish upon these indigestible substances. They would yield him neither flesh nor "fuel." And, having thus come again upon the philosophy of fat" as a source of heat when taken into the stomach (\S 440, bb), the chemist is evidently embarrassed by the contrast which is presented by certain graminivorous and carnivorous animals (\S 440, i); and so he clears the way by the following assumptions, which have only reference, also, to a limited number of two genera of animals (\S 440, cc). The conclusion of the extract is a good specimen of our author's mode of disposing of former observation, and a profitable commentary upon what is requisite in "experimental philosophy" (\S 350, mottoes a-c, and no. 28). Thus:

"We know, in fact, that the graminivora expire a volume of carbonic acid equal to that of the oxygen inspired, while the carnivora, the only class of animals whose food contains fat, inspire more oxygen than is equal in volume to the carbonic acid expired. Exact experiments have shown, that in many cases only half the volume of oxygen is expired in the form of carbonic acid [$350\frac{1}{2}$ n, 440 f, nos. 17 and 18, $447\frac{1}{2}$ f]. These observations cannot be gainsayed, and are far more convincing than those arbitrary and artificially produced phenomena, sometimes called experiments [by the "digestive mixture," retorts, acids, lamp-wick, &c.?]; experiments which, made, as too often they are, without regard to the necessary and natural conditions, possess no value, and may be entirely dispensed with; especially, when, as in the present case, Nature affords the opportunity for observation, and when we make a rational use of that opportunity."

It remains only to say of the foregoing, that the chemist was not duly mindful of the fact that all the principal tenants of the deep, warm-blooded and cold-blooded, are alike carnivorous; and that the exalted temperature of the blubber-whale, the porpoise, &c., breathing, also, with lungs, and in their comparison with the low temperature of their associates that respire with gills, contrasts forcibly with those carnivorous animals whose respiration of oxygen is said to prevent an accumulation of fat. Such, I mean, is the fundamental doctrine of "fat" (§ 440 bb, no. 10). But since animal food, especially fat. contains more of the "fuel" than vegetable food, how does it hap-

pen, according to the foregoing statement as to the relative proportions of oxygen consumed and carbonic acid expired by the graminivorous and the carnivorous animal, respectively, that the former should surpass the latter in the formation of fat?

Wherever, therefore, we look at the "facts" of the organic chemist, we find ourselves not only in the midst of contradictions, but em ployed in refuting assumptions that are opposed by universal experience ($\S 5_{\frac{1}{4}}$). That experience I had employed in the Commentaries for the very purposes to which its adverse assumptions are now consecrated by the disciples of the "improved philosophy" ($\S 349 \ d, 350_{\frac{1}{4}}$).

441, d. In the case of the hibernating animals (§ 441, c), the excessive cold, and mechanical irritation, in rousing the calorific function, operate as a stimulus to the nervous system, and thus restore the organic functions, and the natural temperature as a consequence, along with the other organic products; though the heat more perfectly than any other. In a less degree, cold is a sedative to the hibernating animals (§ $188\frac{1}{2}$, 743). This, also, is an example illustrative of the opposite influences of vital agents, according to their intensity of action, and the circumstances under which they are applied, and of the wonderful adaptation of the natural agents of life to the peculiarities of particular species of organic beings (§ 191, 446 d, 500 o).

The impression of cold, or mechanical irritation, in the foregoing case, is transmitted from the skin to the cerebro-spinal axis, where the nervous power is developed and radiated abroad upon the organic properties of the entire body, by which they are brought into

operation (§ 222-233, 500, 512, &c., 638, 1044, b).

Respiration and other organic functions nearly cease during the state of torpor; but the restoration of heat is far more than commensurate with the progressive return of respiration. Of all the products, an evolution of heat takes the lead, as indispensable to the other important results. This appears to have been seen by Liebig. Nor is there any principle in physiology, nor any facts, which will at all explain the operation of cold in diminishing respiration, or circulation, till it has first reduced the temperature of the surface. And, were the chemical hypothesis true, the hibernating, and the young of other warm-blooded animals, should not sustain the remarkable reduction of heat which is produced by an atmospheric temperature of 45° F., since more oxygen is then consumed than at higher temperatures. There can be no such positive exceptions to a fundamental law. If peculiarity of constitution be assigned as the cause, then is the chemical hypothesis abandoned, and the vital theory admitted.

It is therefore apparent, that the reduction of temperature depends essentially on other causes than diminished respiration. The converse of this must be equally true; and when heat, therefore, is restored, the first step in the process is an increased action of the capillary blood-vessels, through the stimulus of the nervous power (§ 222, &c.), by which an evolution of heat is immediately started; and then begins an increase of the respiratory movements. "We can always hasten respiration," says Bichat, truly, "by making an animal suffer; but an acceleration of the pulse is always prior to that of respiration, which appears to be determined by it."—(See § 484, Exp. C.)

441, e. That is a test. If the heat rises without oxygen, it certainly does not, in such a case, depend upon combustion. The "carriers"

must be regularly supplied (§ 447½, a). I have said that Liebig appears to have been sensible that internal heat is important to the organic processes, though vastly more so in the warm-blooded than the cold-blooded race, and his statement upon this subject is one of his numerous contradictions of the hypothesis which he assumes. Thus:

"It is obvious that the cause of the generation of force is diminished, because, with the abstraction of heat, the intensity of the vital force diminishes. It is also obvious, that the momentum of force in a living part depends on its proper temperature." "The increase of mass is effected in living parts by the vital force. The manifestation of this power is dependent on heat; that is, on a certain temperature peculiar to each specific organism." "The abstraction of heat must be viewed as quite equivalent to a diminution of vital energy."—Liebig's Animal Chemistry.

Now, according to this reasoner, "in the animal body we recognize as the *ultimate cause of all force* only *one* cause, the *chemical action* which the elements of the food and the oxygen of the air mutually ex-

ercise on each other."

We are also told that "the mutual action between the elements of the food and the oxygen conveyed by the circulation of the blood to every part of the body is the source of animal heat."—Liebig's Ani-

mal Chemistry.

But, we have just seen that the same reasoner affirms that these very movements are "dependent on heat" (§ 350, no. $17\frac{1}{2}$, &c.). The cause depends upon the effect, and the effect depends upon the cause (§ 440, f). And how could it be otherwise with an hypothesis so estranged from nature? Indeed, our author not unfrequently quits, entirely, the chemical ground of animal heat, as we have seen of many other assumptions (§ 350), and gives way to the simple dictates of nature. For example,

"Certain other constituents of the blood may give rise to the formation of carbonic acid in the lungs. But, all this has no connection with that vital process by which the heat necessary for the support of life is generated in every part of the body."—Liebio's

Animal Chemistry.

And yet it is both a doctrine of this philosopher in physiology and medicine, that the evolution of animal heat is a purely chemical process, and that carbonic acid cannot be formed in the body without the disengagement of heat (§ 350, no. 17½; § 440, no. 17). Taking, also, in connection the two parts of the foregoing quotation, we have one of those palpable contradictions of a fundamental assumption which are the never-failing characteristic of false doctrines. There is the double affirmation that carbonic acid resulting from any other source than a vital process is not a cause of animal heat, and that animal heat is alone generated by a vital process. (See, particularly, § 440, nos. 6 and 16.) Or, allowing what the language does not admit, the dependence of animal heat upon carbonic acid "generated in every part of the body," we should then have the curious phenomenon in chemistry of the production in the animal body of carbonic acid by a chemical process and by a vital process, while that of the former, the very gist of the doctrine, does not, as avowed, contribute to animal heat (§ 1044).

441, f. Again, it is reiterated. that "the mutual action between the

elements of the food and the oxygen conveyed by the circulation of the blood to every part of the body is the source of animal heat" (§ 350,

no. 3

Now, frogs have a feeble power of generating heat, as have "all living creatures whose existence depends on the absorption of oxygen" (§ 443, c). But, these animals contradict our author's hypothesis as to the "carriers of oxygen," not only in its relation to animal heat, but other important matters, such as the production of force, of notion, &c. (see § 350, nos. 3, 4, 8). Spallanzani, for instance, deprived a number of frogs and toads of the heart, large blood-vessels, &c., and buried them in the snow, along with others which retained their circulation and vivacity. The whole soon became completely torpid, and "appeared as if frozen." In a few hours they were all removed to a warm situation, where all of them began to leap and make their escape; the reanimation being apparently as perfect in those which had been deprived of blood as in those which had not. When exposed to greater degrees of cold they perished in equal times (§ 441½ d, 443 b, 494).

How simple an experiment, therefore, may overthrow the most popular hypothesis in philosophy. It cannot be true of frogs that will leap and jump without blood, as well as frogs with blood, after being "apparently frozen," that their independent source of heat is owing to "the oxygen conveyed by the circulation of the blood," any more than their "amount of motion is proportional to the quantity of oxygen inspired and consumed in a given time by the animal" (§ 350, no. 8).

And then, too, according to our author,

"Since physiology has proved that the globules of blood take no share in the process of nutrition, it cannot be doubted that they play a part in the process of respiration." Especially in white-blooded ani mals.—Liebig's Animal Chemistry.

From all which it is more and more apparent, that "the Reformer" was employed about a plan of human chemistry rather than of animal

chemistry (§ 440, c).

The foregoing subject is farther continued in § 443-445.

 $441\frac{1}{2}$, a. What has been said in the preceding section of the hibernating and cold-blooded animals is true, in principle, of all other animals who suffer only a partial reduction of temperature. The differences do not arise from different fundamental laws, but from different modifications of the properties of life in different species of animals, and at different ages of the same individual (§ 155, 185, 191). There are many animals that approximate the hibernating in their feeble power of maintaining heat; and others, again, which sustain intermediate relations to the more perfect of the warm-blooded vertebrata. "The high temperature," says Edwards, in his Influence of Physical Agents on Life, "which seems to characterize the mammalia and birds, does not belong to them exclusively, since examples of it are found among insects; and, on the other hand, among the mammalia themselves (as the hibernating), which, at certain periods, present the principal phenomena of the cold-blooded vertebrata; and, lastly, a great number of non-hibernating mammalia and birds, in the early periods of their life, show, as far as the phenomena of heat are concerned, a strong resemblance to the cold-blooded animals."

It may be thence inferred, that what is so remarkably conspicuous

in the torpid hibernating animals is only the result of a law that prevails throughout the animal kingdom. This law extends equally to the vegetable kingdom, which possesses a far greater power of generating heat than frogs and other cold-blooded animals. The trees and shrubs which belong to northern climates have, also, exactly the peculiarity of the hibernating animals, while those of tropical regions maintain a greater uniformity of temperature, and are destroyed by a degree of cold in which some northern herbaceous plants spring into

active life, and pierce their way through snow and ice.

441½, b. And this leads me to say, that, through the same law, the warm-blooded vertebrata have their standard of heat modified by climate; and even man himself sustains variations of 1° to 2° F. And, as I have said in my former Essay on Animal Heat, it is important to remark, as showing the entire independence of this phenomenon of respiration, this change does not take place till such as remove from one climate to another shall have been for some time subjected to the new condition of vital stimuli. It is the result of acclimation, and, trivial as it may seem, it is full of the most instructive illustration to a reflecting mind. The phenomenon, I say, is owing to permanent modifications of the vital constitution, and is of the same nature as the change of temperament which the melancholic undergoes on passing from the temperate to the equatorial regions (§ 602), and about which the law of vital habit is interested (§ 561, 585, 602, 603, 1047).

441½, c. It is equally a fatal circumstance to the chemical hypothesis, that the standard of heat is lowest in cold, and highest in hot climates, whatever the amount of clothing, &c., since more oxygen is respired in the former, and, according to our author, a far greater quantity of "fuel" is consumed both by the mouth and by oxygen gas (§ 440, nos. 8, 9, &c.). It is not difficult, therefore, to understand the

bearing of the following statement:

"The most trustworthy observations prove that in all climates, in the temperate zones as well as at the equator or the poles, the temperature of the body in man, and in what are commonly called warmblooded animals, is invariably the same."—Liebig's Animal Chemistry.

And why, again, is the temperature of man higher in tropical than in temperate climates? The reply is another proof of the tampering of chemistry with a subject utterly beyond its reach; since the heat of the tropics operates gradually as a vital stimulus to the calorific function, and thus slowly establishes that condition by which an exalted temperature is determined throughout the universal body (§ 350,

no. 65, 441 c, 445 e).

 $441\frac{1}{2}$, d. Nor may I neglect the striking characteristic of the egg, which possesses the power of resisting cold "in a degree equal to that of many of the inferior animals." This is one of the facts which led Mr. Hunter to believe that the vital properties are capable of generating heat independently even of circulation (\S 441, f), while its greater evolution is seen to be the result of those properties in active operation through the mature organization (\S 65). The former condition, associated, also, with the power of resisting the causes of putrefaction, is a beautiful illustration of the nature of life, that it is an active, not a passive state, that it consists essentially of power, and that its laws are specific. But, how will the combustion hypothesis dispose of the internal source of heat in the egg?

442. a. In respect to the affirmation that "clothing is merely an equivalent for a certain amount of food" (§ 440, no. 11), I have adduced, in my former Essay, many facts to prove that our clothing is greatly a matter of habit, and this is shown by the facts which will be soon presented. It is, indeed, a forcible illustration of the nature of the properties of life, of the dependence of animal heat upon vital action, and of its obedience to the law of vital habit, and to the constitutional law by which all results shall be so regulated as to maintain the integrity of organic processes, and, therefore, a uniform temperature of non-hibernating warm-blooded vertebrata; while, as I have endeavored to show in the same work, the modifications of these processes in hibernating and cold-blooded animals, as well as in the vegetable kingdom, are not only perfectly consistent with what is observed of the non-hibernating warm-blooded vertebrata, but go to confirm the whole philosophy which is founded upon the phenomena of these animals.

There, too, I have shown by an examination of facts, that the rapid change in the power of elaborating heat in early life depends on the same common principle which determines the changes in all other functions and results, that they are all on a par in principle, and that the rapid increase of the resistance of cold in the young of the warmblooded vertebrata proves the vital character of the calorific function (§ 153-159, 441 b, 1047, 1048).

442, b. In illustration of the law of vital habit as it respects the power enjoyed by man of resisting cold (§ 441, c), and in farther disproof of the assumption that a living animal is "like any other heated mass in relation to the temperature of surrounding objects," I shall quote from the Commentaries one of the facts which are there present-

ed for the purpose which is now in view. Thus:

"Mackenzie says, that some of the northern savages follow the chase in the coldest weather with only a slight covering. Lewis and Clark state, that two Indians slept upon the snow during the night in a light dress, when the thermometer was 40 degrees below the zero of Fahrenheit. The man was uninjured; the boy had his feet frozen. Now it is evident that no civilized man could sustain such an exposure. The phenomenon is owing to the power of habit in relation to the forces of life, and is utterly insusceptible of explanation on any other principle."—Commentaries.—See § 1047, 1048.

On the other hand, an individual froze to death in the woods of Peacham, Vermont, on the night of the 7th of June, 1817; notwithstanding, also, he was full, to intoxication, of the most combustible

substance (§ 440, no. 9).

But, again, we are informed by Captain Wilkes, that, when the thermometer was at 40° F., "the Petcherai Indians were entirely naked, with the exception of a small piece of seal-skin, only sufficient to cover one shoulder, and which is generally worn on the side from which the wind blows, affording them little shelter against its piercing influence."

Again, says Captain Wilkes, "On the 11th of March, three bark canoes arrived, containing four men, four women, and a girl about sixteen years of age, four little boys, and four infants, one of the latter about a week old, and quite naked. The thermometer was at 46°

Fh."—WILKES'S Narrative of the United States Exploring Expedi-

tion, vol. i., p. 121, 124. 1845.

The foregoing, in relation to the *infants*, should be considered in connection with what has been ascertained by Dr. Edwards as to the comparative inability of infants to bear a cold atmosphere, when unaccustomed, and with what is known of hereditary constitution (§ 447 h, 540, 561. See, also, *Medical and Physiological Commenta ries*, vol. ii., p. 27, 52, 56, 69-74).

"The power of the Russian Zincali of resisting cold," says Barrow, is truly wonderful, as it is not uncommon to find them encamped in the midst of snow, in slight canvas tents, when the temperature is 30° or 40° below the zero of Fahrenheit."—Barrow's Zincali of Spain.

No two individuals under apparently equal circumstances, of the same health, age, sex, and with the same quantities and qualities of food, clothing, &c., are alike in the power of resisting cold. Place them in a temperature at zero of Fahrenheit, and one will perish while the other will not suffer. One shall enjoy a glow of warmth from athletic exercise, while the other shall perish with the same counteracting means. It is a common event to witness the blasters, in the vicinity of New York, at work in winter with heavy drills in their naked hands, while others, unaccustomed, would be frost-bitten at the same temperature. The difference is manifestly owing in part to a difference in constitution, but especially to the influence of habit, which engenders the power of enduring intense degrees of cold, and which no chemical principles can possibly expound (§ 535–568, 1047).

442, c. The foregoing facts show us, also, how it has happened that animals have spread abroad from the spot where they were created, and become specifically adapted to different climates. The element of their adaptation was implanted in their vital constitution at the time of their creation, and relates to almost all physical agents. And so with vegetables, which may be gradually transplanted from the equator to high northern latitudes, where they also undergo changes of organization (§ 155, 535, 538, &c.). Thus do we also again bring the philosophy of physiology to the overthrow of that infidelity which departs from the Mosaic account of organic Creation (§ 74, 350\frac{3}{4}, h-n).

442, d. Again, do the beasts or the birds of the polar clime change their fur or their plumage when transported to a temperate region? What, for example, answers the white bear, with which we are all familiar? And yet their temperature sustains but a slight change, though a change subversive of the combustion theory (§ 441 c, 441 $\frac{1}{2}$). Here, too, in truth, they consume a far greater quantity of food; and, if the chemist's hypothesis as to an interchange of caloric with the atmospheric air be adopted (§ 440, no. 14), these transplanted creatures should sustain a very exalted rise of temperature. But, upon the physiological action of external heat, as a vital stimulus, the high temperature of a warm climate would much more than compensate for any supposed deficiency of oxygen (§ 440 e, 441 $\frac{1}{2}$ e, 1047).

any supposed deficiency of oxygen (§ 440 e, 441½ c, 1047).

"And then, on the other hand," turning again to man, and as 1 have said in the Commentaries, "are the experiments of individuals subjecting themselves to an excessively high temperature without sustaining any sensible variation of heat. This was fully demonstrated by Blagden, Banks, Fordyce, Solander, G. Home, Dundas, Dr. North, Phipps, Seaforth, and Dobson, who exposed themselves to 260° F."*

^{*} Cl. Bernard's late Experiments of this nature upon animals do not affect these facts or the phiosphy. They were like those of graduated poisons.—1860.

442, c. We see, then, in the various demonstrations, which have now been made, of the power of all warm-blooded, non-hibernating vertebrata to maintain a uniform degree of heat under the greatest vicissitudes of atmospheric temperature that are compatible with life, a proof of a most astonishing law of the living body, in perfect conflict with the laws of caloric as they exist in the inorganic world. "We know it" as exactly as we comprehend the nature and operation of the most precise law in physics. It is, in itself, demonstrative of the government of living beings by specific forces. It establishes a positive distinction between these forces and the organized structure. If I am not right in this construction, I say, once more, let the ground of objection be shown. I mean not the usual denial, or by renewed misrepresentations of my statements. The objections must be founded upon a broad and philosophical survey of all the phenomena of heat that relate to living objects as they may be modified by natural causes, or by morbid states of the system; and the ground must cover the general physiological condition of organized beings. How wide from all this are the assumptions, and those mostly relative to man (§ 440, c), that have been lately consecrated as the true "experimental philosophy" of animal heat (§ 349 d, 1047)!

443, a. As my former Essay embraces an extensive range of inquiry into the facts and philosophy attending the calorific function in the cold-blooded race, I shall now add only a few remarks to what I have already stated upon this subject, and as suggested by the present stage

of my inquiry (§ 441 f, 441 $\frac{1}{2}$ a).

443, b. Frogs and other cold-blooded animals are supplied with capacious lungs; and, however it may be argued that their consumption of oxygen is less than that of warm-blooded animals, they have, nevertheless, the same respiration, nutrition, vital decomposition, and the same "charcoal fire," in the ratio of the food consumed, and yet is their temperature principally regulated by that of the surrounding medium. They also emit a large amount of carbonic acid, which proves a free consumption of oxygen and a liberal supply of food. All this is as essential to frogs as to man; and they equally perish when deprived of atmospheric air, and so of all the cold-blooded finny tribe (§ 350, no. 17½, and § 440, no. 10). And what will chemistry answer to the exalted temperature which attends the inflammations of the cold-blooded vertebrata?

Chemistry must here be consistent, and in being so it necessarily abandons the hypothesis that the evolution of heat, in warm-blooded animals, depends on the union of oxygen with the carbon and hydrogen of the body, and that it occurs in the ratio of that combination. "In the animal body," says Liebig, "the food is the fuel; with a proper supply of oxygen we obtain the heat given out during its combus-

tion." (Also, § 440, nos. 5, 6, 17.)

443, c. The difference in the law regulating temperature is owing to a difference in vital constitution, of which the chemist takes no account (§ 440, no. 12). But, there are also many other peculiarities in the vital phenomena of cold and warm-blooded animals which are due to the same condition of constitution, and by which their relative power of generating heat is shown to depend on a common cause. and which is common to all the phenomena. It is this which is ders cold-blooded animals greatly subject to the temperature of

surrounding medium, but which also enables them to resist its influ-

ence by some 2 or 3 degrees at all seasons of the year.

443, d. If the chemist resort to difference of constitution in explaining the foregoing phenomena, as is generally done, he resorts to the properties and functions of life, and abandons his own ground. In one case he says, it is because they are cold-blooded, and in the other, because they are warm-blooded, and so on. Such, indeed, is the fact. But, is it not because the organization and vital endowments are not adapted to the same generation of heat in one case as prevails in the other; and this, too, when the organization may be in a high de-

gree simple (§ 409, e)?

444. Let us, therefore, settle this question by reference to an animal without lungs, or gills, and in which, also, the temperature is clearly influenced by causes which can alone operate as vital stimuli. temperature, for example, of a hive of bees is at about 90° F., when the air is at 40°, and upward of 70° in winter. Their power of generating heat is also increased during the breeding season. This phenomenon corresponds with the observations that I have made upon vegetables; having found the temperature highest when the leaves and blossoms are putting forth.—(Medical and Physiological Commentaries, vol. ii., p. 75-78.)

445, a. Still more conclusively, than the obvious dependence of organic heat in the cold-blooded vertebrata, insects, &c., upon vital principles, do the phenomena of vegetable heat evince the same great law of organic nature. This subject has been ably explored by John Hunter, and, as I have intimated in the foregoing section, has received a careful attention from myself. Senebier, also, saw the thermometer rise from 79° to 143° F., when placed in the midst of a dozen spathes of the arum cordifolium, at the time of opening their

sheaths. And so Huber, and others.

445, b. That fact, and the ability of plants to generate a temperature often far above the earth or the surrounding atmosphere, are so apparent that they are universally admitted; but obtain from the chemist no farther notice. Indeed, the following is all that we have from Liebig on the subject of vegetable heat. Thus:

"All living creatures, whose existence depends on the absorption of oxygen, possess within themselves a source of heat independent of surrounding objects. This truth applies to all animals, and extends, besides, to the germination of seeds, to the flowering of plants, and to the

maturation of fruits."—Animal Chemistry.

And yet is the "combustive process" always in progress, more or less, in all parts of vegetable organization. The question, therefore, arises as to the motive for not only concealing an important fact, but in thus implying, by circumstantial statements, that no other parts of vegetables "possess within themselves a source of independent heat." The very fact that such a source belongs to seeds in their germinating state, &c., is sufficiently conclusive that it extends to every part of the plant, and "the Reformer" could not have been ignorant that the very egg resists a temperature below the freezing point in virtue of its internal source of independent heat.

But, all this is fatal to our author's hypothesis. Eggs do not consume oxygen, have no "carriers of oxygen," and trees, it is said, do not "burn" like the animal body (§ 302, 3032). Consequently, the

chemist, to carry out his hypothesis of animal heat, must maintain the anomaly that seeds, flowers, and fruits, during their development, are the only parts of the vegetable world that possess "an independent source of heat." The secret of all this will be farther seen in the fol-

lowing passage:

445, d. "The distinguishing character of vegetable life is a continued passage of matter from the state of motion to that of static equilibrium. A plant produces within itself no cause of motion" (see § 350, nos. 7, 8, 10, and § 440, nos. 5, 6, 8, 9, 12, &c.). "In a word, no waste occurs in vegetables. [?] Waste, in the animal body, is a change in the state or in the composition of some of its parts, and consequently is the result of chemical action."—Liebig's Animal Chemistry.

And, again: "Analogy, that fertile source of error, has unfortunately led to the very unapt comparison of the vital functions of plants

with those of animals."—Liebig's Organic Chemistry, &c.

445, c. Thus is the problem solved. There is either no heat generated by plants, or, otherwise, the chemical doctrine of animal heat is radically false. To show how this may be I shall now introduce an abstract of some observations made by myself on the temperature of trees. It is unnecessary to state the mode in which the observations were conducted, or the precautions adopted, as they are recorded in the Commentaries.

On the 9th of April, 1839, in a neighboring forest, the following re-

sults were obtained:

Range of the thermometer in the shade during the observations, which lasted six hours, from 38° to 52° F. Near freezing at sunrise.

A dead upright tree was selected as a standard of comparison. Its diameter was 12 inches. The temperature of this tree, at the close of my observations, was 45° at the centre and in all other parts (§ 440, nos. 14, 15, and 16).

Juglans squamosa,	diamete	er 10 i	nches.	480	Buds slightly enlarging.
Do. do.	44	6	46	490	do.
Fagus sylvatica,	44	10	44	490	Buds swelling.
Quercus tinctoria,	44	7	46	490	No budding.
Castanea Americana,	4.6	12	44	50	do.
Betula nigra,	44	4	4.6	51°	Flowering.
Salix Babylonica,	46	18	61	53	Buds unfolded.

Do. do.	44	3	- 44	65°	do.
Do. do.	46	2	46	67°	do.
Do. do.	**	13	16	68°	do.

Believing that if the vital doctrine of the generation of animal heat were correct, I should find an elevation of vegetable heat as the warmth of the season increased, and the energy of vegetable life became more exalted, on the 19th of the same April I made another visit (\S 441 $\frac{1}{2}$, c).

Range of the thermometer in the shade during the observations,

which lasted five hours, from 40° to 65°.

Temperature of two dead, dry, upright birch trees, one eight inches in diameter, the other six inches, at end of observation 60° in all their parts. Temperature of the earth six inches below surface 47° in shade, at close of observation. Probably 50° at two feet.

Betula nigra,	diameter 1	5 inches.	54°	Buds swelling.
Platanus occidentalis,		6 "	590	do.

Do. do.	٠.	3 "	82°	Buds opening.

445, f. It is abundantly manifest from the foregoing observations that vegetables possess a vital power of generating heat, according to the activity of their organic forces; and I carry the analogy to the animal kingdom. The temperature was not influenced by that of the earth, as seen by the preceding statement. The heat of the latter, however, was not ascertained at the first observation. It appears, also, that the power of generating heat is greater in proportion to the youth of trees. This remarkable fact is not only especially indicative of the vital agencies in the generation of vegetable heat, but is worthy of notice on account of its opposition to what obtains in the animal kingdom in respect to age. It corresponds, also, with observations upon herbaceous plants. The difference depends upon the relative difference in organization and vital properties at the corresponding periods of life. —Comm. Also, § 153-155, 441 b-i, 1054.

445, g. It is a fundamental principle, therefore, that "the general phenomena of the disengagement of heat remain always the same in animals with lungs, in those without them, and in plants, all of which

have an independent temperature."—BICHAT.

446, a. The relation of the nervous power to animal heat is the same as that of all other products of animal organization; its influence, however, being sometimes remarkably pronounced in the elabo ration of heat, as seen in the quick transition of the hibernating animal from temperatures below 40° to upward of 90° F. This subject, however, has been so extensively investigated in my former work that I shall only say now that the elaboration of animal heat does not depend on the nervous power, as often maintained, but, like other functions of animals, is only influenced by it (§ 183-185, 188, 222-233, 489, 492, 500). These are variously affected by varying influences exerted upon the cerebro-spinal and ganglionic systems, as, of course, are also the secreted products in a corresponding manner. In the perfectly natural state, the nervous system has no important agency in the production of the phenomena, but may become powerfully instrumental in modifying the properties, and actions, and products of life, when unusual conditions exist, or when unusual impressions are transmitted to the cerebral and sympathetic centers. Analogy, also, as supplied by the vegetable kingdom, affords the strongest presumptive evidence that the nervous system may have no active participation in the elaboration of heat, in the natural condition of the body, while this induction is strengthened by what is known of other secreted products in both of the animated kingdoms. Still, in respect to the animal kingdom, the mere existence of the cerebral and ganglionic systems, their remarkable properties and susceptibilities, and their intimate connection with all parts of the organization, is, prima facie, conclusive that they have important offices in relation to animals, and that their presence, in the natural state of the complex being, is indispensable to the integrity of every function. This, as will have been seen, has been experimentally ascertained in relation to many; and that unusual, or sudden impressions that are not unnatural, as the operation of the passions, for instance, may be extensively and profoundly propagated from the brain to other organs. It has been fully demonstrated that the natural condition of the secretions depends upon the integrity of the nervous connection between the secerning organs and the cerebrospinal axis; while it has been equally shown that the organic functions, and all vascular action, may be immediately and powerfully influenced by impressions made upon the brain and spinal cord, whether in a direct manner, as in Philip's Experiments, or indirectly through reflex nervous action, as in blows upon the stomach, surgical operations, the action of medicines and of poisons upon the intestinal canal, &c., the ganglionic nerve being the principal medium.

Assuming, then, that animal heat is also a secreted product, it would come philosophically under the common law; and since it appears from experiment, that animal heat depends even more upon the presence of the brain than an imperfect production of gastric juice and other secreted fluids, and may be as powerfully influenced through the nervous system, the physiological analogy between heat and other secreted matters becomes quite apparent; while it explains the remarkable effect of a low atmospheric temperature in developing heat in the torpid hibernating animal (§ 441, 441 $\frac{1}{2}a$); and thus conducts us, also, to the philosophy of the operation of other causes in modifying animal temperature (§ 461, 1032 d, 1044).

To maintain the foregoing conclusion, I have examined, in my former Essay, the merits of Brodie's, Philip's, Chaussat's, and other experiments upon the nervous system, the phenomena of hibernating animals, the modifications of temperature that spring from injuries, diseases, and other affections of the nerves, &c., the admissions of distinguished chemico-physiologists, and other important considerations. Some of these facts in relation to the nervous influence upon animal temperature will appear in the next following section.

446, b. It should be said, however, that it has been stated by some that the experiments of Philip conflict with those of Brodie and Chaussat, which establish an influence of the nervous power over the phenomena of animal heat. But that is an error; since the deduction of Philip himself from his own observations ascribes to the ner-

vous power what is due to the organic power. Thus:

"That the maintenance of animal temperature is a function of the nervous system, properly so called, appears from a variety of facts generally known; the temperature either of a part or of the whole body being lessened by any cause that impairs the action of particular nerves in the former instance, or of the whole nervous system in the latter."—Philip, on Acute and Chronic Diseases, p. 48.

Again he says, "I here consider it as proved, by experiments already laid before the reader, that the evolution of caloric is a function of the nervous influence."—Philip's Inquiry into the Laws of the Vital Functions, Exp. 77. (Also, § 437, c, Note AA p. 1131.)

446, c. It is, of course, erroneously stated by "the Reformer," that, "by the division of the pneumogastric nerves, the motion of the stomach and the secretion of the gastric juice are arrested." The juice is only modified in quality, while it is actually increased in quantity (§

461, 489).

"The Reformer" has also high conceptions of the agency of the nervous system in organic results, notwithstanding they are all exclusively due, in his estimation, to the merest chemical processes (§ 350). "Every thing in the animal organism," he says, "to which the name of motion can be applied, proceeds from the nervous apparatus." Our author, however, is entirely mistaken in his opinion that "the singular idea that the nerves produce animal heat has obviously arisen from the notion that the inspired oxygen combines with carbon in the blood itself." Nevertheless, we are told by our author that "every thing in the animal organism to which the name of motion can be ap plied proceeds from the nervous apparatus;" and we are also told that without this motion there can be no animal heat (§ 350, nos. 3, 17½, 6, 7, 18½, 19).

But, take the ordinary construction of those who mingle together but virtually contradistinguish, the powers and processes of living and dead matter, and impute to the nervous influence no small share, along with chemical agencies, in the production of heat and other products of the living organism, we are asked to sanction one of the most unphilosophical and incongruous medleys of powers, processes, laws, and principles, acting and reacting upon each other, that ever presented itself for well-merited satire. The nervous power is also apt to be regarded by the chemico-vitalist, as by the chemist, a mere chemical agent. But, we shall have seen that this construction is en-

cumbered with difficulties (§ 222, &c., 451 f, 500 nn, $638\frac{1}{2}$).

446, d. The modifying influence of the nervous system upon the generation of animal heat being established not only by experiments, but especially, also, by facts relating to morbid states of the system, to which I shall soon advert, and by all that is philosophical in physiological science, and when we consider, also, how easily and rapidly the nervous influence may be determined upon the vascular system (as in blushing), and upon the organic viscera, we have an intelligible explanation of the operation of a very low degree of cold in recalling into action those vessels upon which depends the exaltation of temperature in the torpid hibernating animal (§ 441 d, 441 $\frac{1}{2}$ a). That the intensity of the cold, like the mechanical irritant (§ 441, c, d), operates, also, in a direct manner, upon the organic properties, as in other instances of foreign agents, is undoubtedly true (§ 189). The law being also universal explains the influences of other causes, in health and disease, in modifying animal temperature, and only regards the agency of respiration, like that of digestion, &c., as being instrumental in perfecting the blood, and thus adapting it to the uses of the various organs which are concerned in the elaboration of heat and other products.

447. a. Whatever is true, in a fundamental sense, of the production

of heat in the natural state of the organic being, must be equally so in its morbid conditions. It is true, we are told by "the Reformer," that "we cannot investigate the laws of life in an organized being which is diseased;" but we have seen that this will not hold in experience or philosophy (§ 303\frac{2}{3}). It serves, however, its useful purpose in the chemical doctrine of animal heat. But, since the truth is just the reverse (§ 160, 163), I shall present from the Commentaries, in this section, a series of facts which contribute an important light upon the physiology of calorification, and upon the general constitution of organic beings. We shall learn yet farther, by this demonstration, that the evolution of animal heat is exactly on a par with all other secreted products, and has a corresponding dependence upon decarbonized blood, and can be regarded in no other aspect (§ 764, c). And here our author's philosophy is consistent, since he imputes alike the formation of animal heat, and all other products, even the circulation of the blood, nay, all diseases, yea, death itself (§ 350, no. 46), to the

union of oxygen gas with the elements of food.

447, b. Indeed, it cannot be too often said, as shown by the question before us, that the phenomena supplied by diseased conditions are often the most important in illustrating the properties and laws of organic beings; and upon no question have they a greater bearing than the one under consideration. Morbid states are only physiological changes, and the resulting products and phenomena are simply modified conditions of such as are more natural, and are dependent upon the same laws, the same causes, the same functions as determine the healthy results (§ 155, 156). This is an undeniable proposition. In the conflict of doctrines, therefore, which are predicated of the perfectly natural phenomena, we should seek for the light of such as emanate from diseased conditions; and here the chemist is even more disqualified for investigation than in the dark mazes of physiology. To him, the vast field of pathology, which every where stamps with falsehood his chemical views of life, is as hidden as undiscovered regions; and since all pathological and therapeutical conclusions necessarily refer to the natural physiological conditions, their impracticability, absurdity, and destructiveness, when deduced from the chemical premises, as clearly demonstrate the shallowness of their The student of organic nature, therefore, appreciates, as he deplores, the ignorance which is received as the light of knowledge (§ 349, d).

447, c. It should be considered, also, in respect to the vast differences in temperature that spring from morbid conditions, whether high or low, the diet is often the same, very spare, or when the temperature is most exalted, as in active forms of fever and inflammation, there is a total abstinence from food. Consider, also, the brute animal under the same circumstances, abstaining totally, yet suffering a

very exalted temperature (§ 440, nos. 1, 4, 5).

I shall proceed, therefore, to a statement of some of the important facts which are supplied by disease, as set forth in my former Essay on Animal Heat. For the authorities quoted, see the Essay.

447, d. Diseases of the brain supply a variety of facts which illustrate our inquiry. Thus, in phrenitis, one arm, or one side of the body, is colder than the other. "That the temperature of a paralyzed part is generally below the normal standard is now universally admit-

ted." That this is owing to impaired vitality, is also shown by the frequent failure of nutrition in the paralyzed part, as well as other coincident phenomena. In a case related by Mr. Earle, he found the temperature at 70° F., in the hand of a paralyzed arm, while that of the opposite hand was 92°. He could also effect a temporary restoration of temperature by electricity and by blisters. "The circulation of the blood did not appear to have suffered, the pulse at the wrist being synchronous, and equally strong with that of the other limb." In an injury of the sympathetic nerve, Chaussat saw the temperature

fall from 104.88° to 78.8° F., in ten hours.

On the other hand, there is a remarkable exaltation of temperature in a part at the invasion of tic douloureux. So, when the nerves are mechanically injured. There was a patient at St. George's Hospital, whose temperature rose 11° F., in consequence of an injury of the spinal column; and this took place when the respirations did not exceed five or six in a minute. It is stated by Dr. Macartney and other observers, that when the principal nerve of an extremity is divided, the temperature of the limb is immediately exalted several degrees. The philosophy of this is well expounded by an advocate of the chemical doctrine. "We should be disposed," he says, "to regard it as due to the temporary excitement of the molecular changes by the irritation produced by the section of the nerve, and propagated to its extremities." Now apply this language to the exaltation of temperature in any inanimate substance, however produced, and we may appreciate the merits of the chemical solution in the former instance.

"In some subjects of insanity," says Dr. Cox, of Fish Ponds, "who were under strong coercion in the horizontal position, with the head much elevated, whose face was red, and the vessels turgid, the difference of heat was very obvious, varying 10, 12, and even 15 degrees."

In apoplexy, the temperature has been known to rise, after death, a number of degrees above the natural standard; and its persistence has been found so uniform in apoplexy, that Dr. Cheyne regards it as a diagnostic symptom. The temperature of a lawyer, dead of apoplexy, was so high at twenty-four hours after death, that Portal delayed an examination of the body. The same phenomenon is observed after death from other diseases,—especially when the nervous system

has been unusually concerned in the morbid process.

"In opening bodies at the Hôtel Dieu," says Bichat, "I have observed that the time in which they lost their animal heat was very variable; that a body continues warm a greater or less time, especially among those who have died suddenly of an acute affection, in the paroxysm of an ataxic fever, for example, or by a fall; for those who die of a chronic disease, lose almost immediately their caloric. The difference in the first is often three, four, or even six hours. This phenomenon arises from the fact, that whenever death is sudden, it interrupts only the great functions; the tonic action of the parts continues for a greater or less time after. Now this action disengages a little caloric from the blood that is in the general system." "When the disengagement of caloric has ceased in the body, that which remains in it becomes in equilibrium with that of the external air, according to the general laws of this equilibrium. Now these laws being uniform, their effect would be the same in every case."

Again, sometimes the temperature in apoplexy is greatly depressed

before death takes place; and this, too, while the circulation is such as to admit of blood-letting. Two cases of violent apoplexy ("violento paroxysmo") are recorded in the Ephemerides Germanii, in which the blood, as it flowed from the veins, was actually cold. Morgagni mentions an instance of another affection in which the blood flowed "in an icy cold stream" from the arm. Thackrah saw a similar phenomenon. So, also, De Haën. I need scarcely say, also, that when respiration is extremely labored and slow in apoplexy, the natural temperature is often either undiminished or considerably exalted. Our familiarity with the fact, however, only increases its importance, and shows, by the frequency of the coincidence, that respiration can be only remotely concerned with the generation of heat.

Here is another variety in apoplectic affections:

"While a gentleman," says Mr. Hunter, "who was seized with an apoplectic fit, lay insensible in bed, covered with blankets, I found that his whole body would, in an instant, become extremely cold in every part, continuing so for some time; and as suddenly would become extremely hot. While this was going on alternately, there was no sensible alteration in his pulse for several hours."

Here is another case, from the same observer, not less fatal to the

theory of respiration:

"Å man fell from his horse, and pitched on his head, and produced all the symptoms of a violent injury. There was concussion, and perhaps extravasation of blood. The pulse was at first 120, but came to 100, and sometimes to 90, and was strong, full, and rather hard. He was very hot in the skin, but breathed remarkably slow, only half the common frequency." Other injuries exalt the temperature in other modes of an equally vital nature. Thus, extirpation of the kidneys through the increased stimulus of the blood, often raises the temperature of the body more than six degrees.

The following case, by Mr. Hunter, also, seems also to have been

intended for our special purpose:

"February, 1781, a boy, about three years old, appeared not quite so well as common, being attacked with a kind of shortness of breathing in the night. It had become excessively oppressive about five o'clock on Sunday morning, so difficult that he appeared dying for want of breath. The common rate of breathing in such a boy is about thirty inspirations in a minute. At 10 o'clock, he was drawing his breath with a jerk,—about two and a half inspirations, or even less, in a minute. Pulse sixty, faint, slow. On tying up the arm, the vein did not appear to rise in the least, so that the blood did not go its round. Body purplish, especially the lips. He had a fine warmth on the skin all over the body, although in a room without a fire,—not covered with more clothes than common in the month of February, with snow falling at noon."—HUNTER.

This, and the preceding case, appear to differ in some physiological details. In the former, the disposition of the capillaries to generate heat seems to have been a good deal determined by the cerebral influence; in the latter, the alteration of the vital forces was probably owing to other causes. Like other cases, therefore, which I have recited, they serve, by their variety, to illustrate the vital nature of the principles which are mainly concerned in the production of animal heat. But, standing alone, they must either subvert the hypothesis

which concerns respiration, or we must have a chemical theory for the natural state of the body, and a vital one for its morbid conditions. This would be clearly absurd; at least, if there be any such thing as philosophy, or any consistency in the powers and functions of life. These examples show us, also, how very probable it is, that all our chemical hypotheses in relation to life are the mere offspring of habit, or imitation, or of narrow observation. It is certainly hard to give up the fruit of great toil and research; but it is harder for others to endure it, who prefer to be instructed by the voice of nature, rather than by artificial results.*

I shall present other examples to the foregoing effect, as supplied by morbid conditions of the system; since these, more than experi-

ments, conduct us to the true philosophy of animal heat.

Every physician is familiar with the variations of temperature in disease; which, indeed, engage his attention in almost every case. It is often exalted when respiration is slow, and again depressed when breathing is hurried; and it is one of the most common phenomena to find it different, by many degrees, in different parts of the body, and under every variety of respiration and circulation. It will, therefore, be my purpose only to mention a few of the more unusual instances.

Dr. Philip has known the temperature of the skin at 74° Fh. in the cold stage of an intermittent, while in the hot stage it rose to 105°. Craigie found it at 107°, and 109°. Here the respiration and circulation are often most accelerated during the cold stage. This, with the vast difference in temperature, refers the depression of heat to other causes than the mere constriction of the capillaries in the cold stage. Here, too, as in all analogous cases, we have a coincident diminution of all other secretions. Piorry has seen the temperature in six cases of typhoid fever varying from 108° to 117°; and in one of these, the blood was at 113° Fh. In phthisis, he has known it at 114°, and in a case of pneumonia, the blood was 113°. Prevost found the temperature of the body at 110° in tetanus. Granville says it sometimes rises in the uterine system to 120° Fh., and that it depends on the degree of action in the organ. In hydrophobia, where respiration is probably always accelerated, Currie found that "there was no increase of animal heat in any one of five cases."

"The Reformer" says that, "for a given amount of oxygen the heat produced is, in all cases, exactly the same;" and that "the consumption of oxygen in equal times may be expressed by the number of respirations' (§ 440, no. 5; 441, b). But, in stating this, he did not reply to the following interrogatories propounded in my former Essay. Thus: How is the natural temperature maintained in consumption, where respiration is sometimes so greatly impaired as not to be compensated by any acceleration of its movements? Or why is it, when the lungs are impervious from condensation, and their function otherwise greatly impaired by destructive ulceration, the heat rises habitually in the afternoon, even to 114° Fh., and that, too, without any previous reduction of temperature, and often without any increase of respiration?

^{*} I commend, also, to our minute philosophers Mr. Hunter's experiment upon the carp. It was partly intended to illustrate a vision of our author, by which, as he says, "like other schemers, he thought he should make his fortune." But our author had not only the good sense to abandon it, but the magnanimity to hold it up as a weakness of the human understanding.

Why do the palms of the hand "burn" when the rest of the surface is cool? Will chemistry explain? Will it explain, also, at the same time, the analogous phenomena, and the vicissitudes of heat and cold, the quick transitions from one to the other, that are forever perplexing the physician in his treatment of continued, remittent, and intermittent fevers? Will chemistry maintain, in conformity with its doctrine, that these periodical evolutions of heat are due to paroxysmal combustions of the tissues, especially where little remains to undergo the process, respiration obstructed, and yet a high exaltation of temperature? Explain, I say, all this in conformity with the "oxygen and fuel" system, and vitalism will surrender to the devices of human

ingenuity.

Why is it, that when the general temperature of the body is at some 85° Fh. it may exist at the scrobiculus cordis at 106° and upward?* Mr. Malcolmson states, that in the Asiatic cholera "the skin is sometimes colder during life than after death, and a partial rise of temperature over the trunk is frequently a fatal symptom." I have witnessed the same phenomena. Mr. M. also observes, that beriberi supplies analogous instances; and that when the temperature was extremely reduced, "it was not different when the limbs were closely wrapped in woolen, or when the thermometer was held between the soles of the feet or hands, and free evaporation carefully prevented." Is it not obvious, in these instances, that the power of generating heat was lost in consequence of modified vascular action; and if so, then the generation of heat depends upon vascular action, and is, of course, a vital product. This, too, is most emphatically shown, in the instances here and elsewhere stated, by the "partial rise of temperature over the trunk" just antecedently to death. It is analogous to those cases in which profuse perspiration breaks out in syncope, or as patients are in the act of expiring. It grows out of a powerful reflex nervous influence upon the vires vita, by which a sudden change of action is induced in the elaborating vessels (\\$ 637).

Why is the temperature often exalted in congestions of the lungs, "where life is endaugered by diminished communication with the air;" and why, in such a case, will "the abstraction of blood diminish the power of producing heat,"† although, by this means, we extend the communication of the lungs with the air? Or, again, in congestions of other organs, when the respiration is natural, the circulation in the lungs unobstructed, but the animal heat greatly reduced, why does it happen that the abstraction of blood will at once exalt the temperature without affecting the respiration, or even increasing the force or frequency of the general circulation (§ 961, d)?

In the latter cases, the rationale appears to be, as I have endeavored to explain in my Essay on Blood-letting, that a direct change is exerted by the abstraction of blood upon the instruments of all vita, actions, by which the calorific, as well as other functions, are improved or restored. It is here, animating these minute vessels, that we shall find the principles residing by which we are to account for all the remarkable phenomena of animal heat. As the operation of these forces is modified, whether by natural or artificial causes, so will be the phenomena which depend upon them. This is universally true

^{*} See my Letters on the Cholera Asphyxia, and other authors upon this disease.
† Edwards, on the Influence of Physical Agents on Life, p. 275.

of all the manifestations of the organic forces, whether they consist of vital phenomena, or of material products. The function of respiration is just as much concerned with one as with the other, and probably no more. It aids, like the chylopoietic viscera, in perfecting the great material from which bile, urine, the gastric juice, &c., are elaborated by the vital properties and their instruments. And just so is

respiration concerned in the production of animal heat.

Again, "sympathy," says Bichat, "as we know, has the greatest influence upon heat. According as this or that part is affected, there is disengaged in others more or less of this fluid. How does all this happen? In this way: the affected organ acts sympathetically on the tonic forces of the part; these being raised, more caloric than usual is disengaged. It is precisely the same as in sympathetic secretions or exhalations. Whether the vital forces are raised by a stimulus directly applied, or by the sympathetic influence they receive, the effect

that results from it is exactly the same" (§ 1044, a, b).

And again, the same accurate philosopher: "Each system has its own degree of heat." This fact was not so well known in Bichat's time as now. But it was his induction from general principles. I shall only advert to the example of the dog's nose, which is familiar to all. Hunter, however, rendered the fact sufficiently obvious;—Davy and others have confirmed it. Now, how exactly all this corresponds with what is known of the vital endowments of particular organs. Where they are most strongly pronounced, there the temperature is apt to be highest, there the phenomena of organic life predominate, and there it is that morbific causes make their most frequent and deep impressions, and develop the most exalted temperature.—(See Essay on Venous Congestion, § 8, 9, in Comm., § 1045).

447, e. Finally, I come to what I consider an experimentum crucis, supplied by an able philosopher, and by one of the most able defenders of the chemical doctrine of animal heat. He states that great differences arise as to oxygen, during the respiration of atmospheric air:

"The real causes are chiefly certain inherent differences in the state of the venous blood, which are indicated, indeed, by other physiological facts, but by none so unequivocally as by this variety in the power of altering the oxygen of atmospheric air. The first cause is a difference in the degree of venosity or venalization of the blood in passing through the capillaries." The second and last "cause of diversity in the action of venous blood on atmospheric air is a difference in the proportion of coloring matter contained in the blood."

Now, if the chemical doctrine have any foundation, its advocates should show that there is a greater, or, at least, as great a consumption of oxygen in those states of the system which are attended by an exaltation of temperature, as in the natural condition of the body. On the contrary, however, they show just the reverse of this. Thus, the

high authority whom I have just quoted:

"The inferior action of the blood on the oxygen of the air in its passage to the arterial state simply indicates, that it is less removed from a state of arterialization, that is, partakes less than usual of the characters of venous blood. Accordingly, the least alteration of oxygen invariably occurs in those febrile diseases where the circulation is much excited, and the respiration at the same time free. These conditions exist most especially in acute rheumatism; and it was, there-

fore, in cases of this disease that the four instances of slight action (on the air) formerly mentioned have occurred. On all these four occasions the blood was evidently more florid than usual, and in the instance where the loss of oxygen was only 0.57 of a cubic inch, the stream from the vein was so bright, that the gentleman who opened it had at first some suspicion that he had opened the artery."*

Here, also, we have, from a distinguished chemist, a philosophical resort to the modified condition of the system in disease, for an interpretation of the wonderful peculiarity of living organized matter in

manifesting the power of generating heat.

447, f. We have thus again seen that the chemical hypotheses which immediately concern the functions of respiration are surrounded by too many exceptions to come within the pale of nature. These exceptions meet us every where in the habitual state of the animal, and in the history of disease they become almost as multiplied as the individual cases. Here it is that we may most successfully contemplate the law and its operations, in the various modifications which it sustains from the influence of remote causes, and those within the body. Among the latter, are those of the mind, and the derangements to which the lungs are liable, both in their general and organic functions. But far more frequently, and more profoundly, is animal temperature directly exalted, or diminished, by affections of the stomach and of the nervous system. I need scarcely repeat, it would be absurd to have one theory to explain the phenomena of heat in health, and another in disease. It would be a violation of all philosophy, as well as a reckless disregard of all facts. According to the common designs of nature, there cannot be one law for the generation of heat in the healthy state of the body, and another which determines the exalted heat of fever and of local inflammations. While the various functions proceed in their natural manner, the evolution of heat, like the other products, remains without any radical alteration. But when the latter are disturbed in their natural character, the former is liable to corresponding variations, which can be explained only on the principle that the power of generating heat is as much an attribute of vitality as any that may be concerned in the process of disease, and that their various modifications are constantly determined by analogous causes. It is a broad, fundamental principle, that "the general phenomena of the disengagement of heat remain always the same in animals with lungs, in those without them, and in plants, all of which have an independent temperature."

447, g. Some chemical philosophers, like the able Edwards, in treating of animal heat, have called to their aid the "constitution" of animals to explain certain anomalies which defy the chemical hypothesis. We hear much about the "power of the system to generate heat," without being let into the secret in what that constitution, and that power, consist. To allow that the forces of life have a large and uniform share in the generation of animal heat, would make a repulsive medley, in its connection with the chemical hypothesis. Now that "constitution," and that "power," are something more than ideal; something different from the organized structure; for, in the latter case, many variable phenomena, in adults, proceed from unvarying

conditions of structure (§ 1047).

^{*} Dr. Christison, in Edin. Med. and Surg. Journ., 1831, p. 101, 102.

Just so is it with all the varying conditions of animal heat. In health, the varieties are owing to peculiarities in the natural condition of the vital properties; in disease, they arise, like all the other changes, from morbid alterations of those properties; and, if the blood sustain any want of its proper influences from defect of respiration, this will contribute toward the modifications of temperature in the same way that it affects the other results of life, and, I apprehend, in no other.

Although Dr. Edwards derives some illustrations regarding the connections of the phenomena of animal heat with respiration from certain morbid conditions of the body, as in asphyxia from carbonic acid, syncope, the cold stage of intermittents, &c., yet it is manifest that he looks upon disease as supplying facts which it is prudent not to investigate. "The question now is," he says, "what is the influence of the respiratory movements on the temperature of the body, when they are raised beyond the rate of health? We cannot answer this inquiry by observations on the sick. The circumstances are then too complicated to admit of our deriving conclusions from them."—Op. cit.

In this conclusion I do not at all agree. It is an unwarrantable abandonment of nature for the contrivances of art. Morbid conditions, above all others, give us a clew to the true philosophy. The vital properties are altered by disease, and with them there is a change in all the phenomena and results, of which the modifications of animal heat are one. Hence, it appears to me, that a very obvious "conclusions"

sion" may be deduced.

447, h. In respect to the natural differences in constitution that are denoted by apparently contradictory facts in relation to animal heat, they are as clearly constituted by natural modifications of the same forces, which are as much, or more influenced by other causes than by respiration; whose power of evolving heat in young animals is greatly and rapidly depressed by the operation of cold, notwithstanding the respiration is accelerated during the first stages of the decline of temperature; but which, again, as the same animals advance in life, acquire the power of completely resisting the same cause without the former acceleration of the respiratory movements; "the animals thus passing from the state of cold-blooded to that of the warm-blooded," while in the hibernating mammalia generation of heat still goes on although respiration have come to a stand, or, when the cold becomes intense, is carried to its highest pitch by the very cause which had produced its great decline; or, the same forces maintain a uniform state of heat when the respiratory movements are greatly accelerated by external heat, and resist equally the heat of the surrounding medium; or, such is their natural susceptibility they may be so influenced by season, that their power of producing heat is said to be less when its production is greatest; which power "may be varied, in some, by suitable food and a graduated temperature;" which "is generally diminished in natural sleep, though modifications occur which change the relation;" which is so modified in the cholera asphyxia, that the temperature may greatly fail while respiration is accelerated. and the lungs free from congestion; or, is undiminished in asphyxia from carbonic acid, "when the respiratory movements are no longer seen;"* or may attain, as in apoplexy, preternatural vigor after respiration and circulation have entirely ceased.

^{*} Portal says that the heat has been known to remain very high in these cases, as in apoplexy, for many hours after death.—Sur l'Apop

"Constitution," then, and the "power of generating heat," manifestly relate to the vital properties, and to nothing else. The united operation of these powers, through their instruments of action, results in the elaboration of bile, gastric juice, heat, &c., from the blood. That particular determination by which they eliminate heat, in all parts of the body, may be called a law, though it is but the joint result of the vital powers, concurring in a certain manner to a specific effect. The result is variously affected by climate, season, the quality and quantity of food, stimulants and sedatives, cold or warm air applied externally or to the lungs, by morbific agents, and other causes; or, as the vital properties happen to sustain peculiarities in relation to individuals, age, &c., so will the generation of heat be modified when respiration is exactly the same; and along with those modifications of heat are variations, more or less coincident, of other products. The causes are obvious from the effects. The former are few and simple; the latter are diversified without end (§ 1047).

Most of the reasoning which abounds in authors who believe animal heat to depend specifically upon respiration, or the result of a chemical process, consists in reconciling difficulties by referring them to the vital powers, and sometimes to the entire exclusion of the chemical hypothesis. True, they do not say vital powers. They would otherwise be non-conformists. They speak of "constitution"—"the power of evolving heat,"-yet turn into ridicule the only true philosophy, and the only possible thing which they themselves can mean. If they hazard the "term vitality," it "is employed for the want of a better," but "without any connection with the mystification which sometimes attends its use;" while others, like Dr. Elliotson, can see nothing in "animal heat," "but a peculiar state only;" and here, as in the case of "vitality," Dr. E. "adopts the common language in speaking of animal heat," to make the subject intelligible.

It is from the blood, like all other animal products, that heat is derived. And since decarbonization, and, perhaps, an absorption of oxygen, is indispensable to the healthy performance of all other functions, it is doubtless important to the generation of heat; though manifestly less so in the latter instance, since we see the evolution of heat sometimes going on when respiration is nearly, or quite extinct; while in the cold-blooded animals it exerts but little, if any, influence upon temperature. Decarbonization of the blood, and probably the absorption of oxygen, are among the numerous processes by which its vivification is perfected, and by which it is prepared for an elaboration of the various animal products, and in animals of a certain constitution for the evolution of heat. When respiration ceases, all the most important functions immediately fail; but it is remarkable that the evolution of heat appears to be the very last.

I conclude, therefore, that the elaboration of animal heat, and all other secretions, are on a par in regard to principle. It is true, a certain proportion of latent heat may be extricated by the conversion of blood into the solid parts. But this would be counterbalanced by a corresponding change of the solids, particle for particle, into fluids. This appears to me to be fatal to a late doctrine which imputes animal heat to this cause; as well, also, to the condensation of gases. Besides, what becomes of the principle of condensation where the temperature rises after apparent death (§ 447, d)? Where is oxygen gas?

447½, a. In my former Essay I have also considered the hypothesis relative to the absorption of oxygen gas by venous blood, and the conditions under which it was supposed to unite with carbon, in the process of respiration. It only remains now to state circumstantially the views entertained by Liebig upon this subject.

1. "During the passage of the venous blood through the lungs, it absorbs oxygen from the atmosphere. Farther, for every volume of oxygen absorbed, an equal volume of carbonic acid is, in most cases,

"The globules of venous blood experience a change of color, and

this change depends on the action of oxygen."

"The red globules contain a compound of iron; and no other con-

stituent of the body contains iron."

"The compound of iron in the blood has the characters of an oxvdized compound." "No other metal can be compared with iron for the remarkable properties of its compounds."

2. Many "observations, taken together, lead to the opinion that the globules of arterial blood contain a compound of iron saturated with oxygen, which, in the living body, loses its oxygen during its passage

through the capillaries."

The last quotation is a universal theory with our author. By it "the Reformer" interprets all motion, the generation of all power in the animal body, the circulation of the blood, inflammation and fever, obesity and emaciation, the various phenomena of life, and even death itself. "The oxygen of the air and the carriers of oxygen" are all in all. The "carriers lose their oxygen during their passage through the capillaries," when a "combustion of the tissues is set up," which is the true and only cause of the principle of life, of its extinction at death, and of all the unique phenomena of the animal creation (§ 350, nos. 3, 4, 5, 7, 8, 9, 10, 15, 18, 19, 46; § 440, nos 1 4, 5, 6, 8, 9, 10, 11, 12, 14, 16, 1054).

It is not, therefore, remarkable that "the Reformer" should have considered animal heat as life itself,—both the cause and effect of life (§ 441 e, 440, nos. 8, 9, 11, 12, 14, 16),—since every known process and result in the animal "machine" is due to "combus-

tion."

3. "The compound, rich with oxygen (no. 2), passes, therefore, by the loss of oxygen, into one far less charged with that element. One of the products of oxydation formed in this process is carbonic acid. The compound of iron in the venous blood possesses the property of combining with carbonic acid, and it is obvious that the globules of the arterial blood, after losing a part of their oxygen, will, if they meet with carbonic acid, combine with that substance (§ 440 f, no. 18, and h). When they reach the lungs, they will again take the oxygen they have lost; for every volume of oxygen absorbed, a corresponding volume of carbonic acid will be separated; and they will again ac quire the power of giving off oxygen."

"In their return toward the heart, the globules which have lost their oxygen combine with carbonic acid, producing venous blood; and when they reach the lungs, an exchange takes place between this

carbonic acid and the oxygen of the atmosphere."

"The organic compound of iron, which exists in venous blood, recovers in the lungs the oxygen it had lost; and, in consequence of

this absorption of oxygen, the carbonic acid in combination with it is

separated."

4. "Hence, in the animal organism, two processes of oxydation are going on; one in the lungs, the other in the capillaries. By means of the former, in spite of the degree of cooling, and of the increased evaporation which takes place there, the constant temperature of the lungs is kept up; while the heat of the rest of the body is sup-

plied by the latter."—Animal Chemistry (§ 438, b, c).

447½, b. If, therefore, we exclude the vegetable kingdom as an important element in our interpretation of organic heat, we shall have seen by this fundamental hypothesis as to the globules of blood that there can be no doubt that the general theory of animal heat has been founded upon certain speculations relative to a limited number of red-blooded animals, and often, as we have reason to suppose, to man alone. It takes no cognizance of all those white-blooded races that possess no ferruginous globules, and therefore no "carriers of oxygen gas," and whose temperature in some instances, as in the bee, approximates that of the human race (§ 444). However much a general theory may draw upon contingencies for its support, it must be universally applicable to the same combination of phenomena. It will not answer to have "ferruginous carriers of oxygen" for one class of animals, and something very different for another class, to explain what is common to both.**

 $447\frac{1}{2}$, c. In the former Essay I have devoted to the questions relative to the elimination of carbon from the blood, and the formation of carbonic acid, all the attention which the subject might otherwise now require; and in another section of this work an argument is presented to sustain my former conclusions (§ 419). In the foregoing Essay I have endeavored to show that the distinguished chemical theorist,

Dr. Edwards, is right in his position, that

"Carbonic acid is not formed at once, in the act of respiration, by the combination of the oxygen of the air with the carbon of the blood,

but is entirely the product of exhalation."—EDWARDS.

I there urged, that the carbonic acid evolved from the chest does not exist in the state of that inorganic compound in the blood; but that the carbonaceous matter exists in intimate union with the blood, from which it is eliminated in the form of carbonic acid gas by the joint agency of the pulmonary mucous tissue and oxygen; the former taking the lead in the process (§ 419). The carbon of the blood is thus readily convertible into carbonic acid while undergoing that special vital process of the mucous tissue. I may quote from the Commentaries a remark which is not less extensively applicable in these Institutes. Thus:

"Before going farther, I may say, that, in having employed, as I shall continue to do, the established phraseology of chemical science, I have assigned many reasons in my first volume, as I shall others in my Essay on Digestion, for believing that every product of the animal system, including the excrementitious, is differently constituted in its elements from such as result from the agency of chemical forces; that, what we may find in our test glasses and crucibles has been really different before, or at the time of its elimination from the body. Chemical changes may accrue in excrementitious substances immediately after their elaboration; and the ultimate combination

^{*} I have abstracted blood resembling milk, of a slightly reddish tint, from a patient in an ardent state of remittent fever, soon followed by recovery.

may be uniform, especially where, as in carbonic acid, only two elements are ultimately concerned."—Med. and Phys. Comm., ut cit.

Although our author, while employed about the chemical rationale of organic products, speaks of them as though they were generated by the living organism as he is accustomed to observe them in the laboratory, and looks upon carbonic acid as equally the product of the organization as of the combustion of carbon (or, in his own language, "the animal body acts in this respect as a furnace which we supply with fuel," § 440, no. 1), he now and then yields to the force of facts, and even allows, at one time, that the iron of the red globules exists in the state of an "organic compound" (no. 3, this sec-

tion).—Note R p. 1123.

447½, e. It is also important to consider that the absorption of oxygen from the air, and the excretion of carbonaceous matter, take place through a highly organized tissue, and the moment life ceases, so also do these processes, notwithstanding artificial respiration. The same tissue, too, which performs those functions, secretes, also, a mucous fluid. This secretion being distinctly the result of vital action, it will hardly be insisted that the same tissue is simultaneously performing, in respect to another product, a mere chemical, or the physical functions of endosmose and exosmose (§ 419). There is here the same incongruity as we have seen of the chemical theory of digestion, in establishing antagonizing processes for the conversion of food into chyme (§ 358, 360, 374).

 $447\frac{1}{2}$, f. It remains now to notice, of the foregoing quotations (§ $447\frac{1}{2}$ a, nos. 3 and 4), another of those extraordinary mistakes in fundamental principles, and where pure chemistry is concerned, which so much abound in our author's work on *Animal Chemistry*.

In the first place, we had been told again and again, that "animal heat is produced by the combination of oxygen with carbon or hydrogen," and in no other way (§ 440). That is the combustion theory,

and without it there is no animal heat (§ 440, no. 6).

By referring, however, to § 447½ a, 2 and 3, it will be seen that oxygen does not unite with any combustible substance in the process of respiration, but only with an oxyd of iron; and that in no. 4, it is asserted that by this supposed union of oxygen with iron "the constant temperature of the lungs is kept up, in spite of the degree of cooling, and of the increased evaporation which takes place there." "Hence," says Liebig, "in the animal organism, two processes of oxydation are going on; one in the lungs [the union of oxygen with an "organic compound of iron"], the other in the capillaries [the union of the absorbed oxygen with carbon, &c.]. By means of the former, in spite of the degree of cooling, and of the increased evaporation which takes place there, the constant temperature of the lungs is kept up; while the heat of the rest of the body is supplied by the latter."—Liebig.

The general concurrence, even of chemists, in the foregoing exposition of the laws of animal heat, can alone justify any farther comment. But the work must be efficiently done to operate as a perpet-

nal barrier to the pernicious invasions of chemistry.

I say, then, in whatever aspect the foregoing statement may be regarded, it is deeply discreditable even to chemical philosophy. In the first place, a distinct chemical provision is made for the "lungs" and for "the rest of the body," respectively, for the maintenance of

the same uniform temperature in all the parts, while it is assumed that the union of oxygen with the iron of the blood is exactly equivalent as a source of heat, and under all circumstances, to the union of oxygen with carbon and hydrogen in the process of combustion: without regarding the auxiliaries, "clothing," "laborious efforts," "cold water," &c., which are brought to the aid of the chemical process in "the rest of the body."

But that is not the worst of the doctrine; for it denies to the lungs any participation in that combustive process which is not only the foundation of animal heat "in the rest of the body," but of every result which appertains to life. Chemistry, of course, abandons the ground; but it must carry with it a mortification which is due from the physiologist (§ 350, mottoes a, b, c, d, e), and a farther recognition of the justice of the rebuke administered by Hunter (§ 350, no. 97).

It will have been seen, however, that the foregoing is only one of a constant succession of blunders whenever the chemist trespasses upon organic life. And were we to look yet farther into the last of the series, it would be found laden with objections. The physiologist, for example, has a right to insist that the general doctrine shall apply as well to the lungs as to the "rest of the body," and that there is an equal combustion of both. The chemist, therefore, necessarily places the temperature of the lungs at 1960, in making the union of oxygen with the iron of the blood equivalent to the combustive process. And having thus rectified the hypothesis, we find ourselves presented with a fundamental auxiliary to the general principle, that its integrity may be preserved in the lungs which are beyond the reach of "clothing," while the surface of the body, which is more exposed to the operation of cold, is left to the general principle supported by the contingencies of dress, along with those other provisions, "food," "laborious efforts," "candles," &c., that are designed for the maintenance of the same temperature in "the rest of the body" which is accomplished by the two chemical processes in the lungs (§ 440, nos. 10, 11, 12, 13, 14).

While now adverting to the subject of carbonic acid in its supposed relation to animal heat, I will place in contrast two doctrines by our author, which make up a part of his system of pathology, as the best evidence I can offer, in parting forever with Organic Chemistry, of the sincerity of the motives which have governed the demonstrations I have endeavored to make in behalf of sound philosophy, the honor of my profession, and the best interests of man (§ 1 b, $350\frac{1}{4}$, $376\frac{3}{4}$ b,

820).

"We find; in point of fact, that

CHEMISTRY as founded on the basis Physiology as founded on the baof "Experimental Philosophy." sis of "Experimental Philosophy."

"If we consider the fatal accithe living blood is never, in any dents which so frequently occur in state, saturated with carbonic acid; wine countries from the drinking that it is capable of taking up an of what is called feather-wine, we additional quantity, without any can no longer doubt that gases of apparent disturbance of the func- every kind, whether soluble or intion of the globules. ters, more carbonic acid must ne- This poisonous wine is wine still cessarily be expired than at other in a state of fermentation, which is Less, however, will be increased by the heat of the stomach. The carbonic acid gas which is disengaged, penetrates through the parietes of the stomach, through the diaphragm, and through all the intervening membranes, into the aircells of the lungs, out of which it displaces the atmospheric air."-LIEBIG'S Animal Chemistry (§ 350, nos. 24, 43).

448, a. The main objection to the vital doctrine of animal heat, or that which places it on the common ground of secreted products, seems to have arisen from a difficulty of comprehending the manner in which heat can be generated by any process than such as has been most familiar to the senses. The objectors, however, have no difficulty in assuming that the "nervous power governs the chemical forces in the formation of animal heat." This admission of the instrumentality of the nervous power is founded upon certain irresistible facts which chemistry cannot appropriate, and goes very far in allowing the force of analogy which refers the production of animal heat to the same great principles of life that are known to preside over all other products of animated beings.

448, b. But, is there any stability to the doctrines which relate to the evolution of caloric in the inanimate world? None at all. Even

Lavoisier's hypothesis is overthrown.

"A new theory is, therefore," says Turner, "required to account for the chemical production of heat. But, it is easier to perceive the fallacies of one doctrine, than to substitute another which shall be faultless, and it appears to me that chemists must, for the present, $b\epsilon$ satisfied with the simple statement, that energetic chemical action does, of itself, give rise to increase of temperature."—Turner's Chemistry.

448, c. Let us now borrow from the same distinguished chemist, an example by which the foregoing statement is sustained, and which will remove all difficulty as to the problem that animal and vegetable neat are elaborated by the organic force through the instruments of vital action, according to the other products of organic beings. Facts will receive their proper interpretation, an important analogical induction will remain inviolate, while the uniformity of other secreted products, coinciding with the uniformity of temperature, or each varying together under the same vital influences, expounds the latter phenomenon and corroborates the vital interpretation. Thus, Turner:

"It is a well-known fact, that increase of temperature frequently attends chemical action, though the products contain much more insensible heat than the substances from which they were formed. This hap pens remarkably in the explosion of gunpowder, which is attended by intense heat; and yet its materials, in passing from the solid to the gaseous state, expand to at least 250 their volume, and consequently render latent a large quantity of heat."-TURNER.

448, d. Now, although it be allowed that phenomena of the foregoing nature may have been explained by supposed differences between specific and latent heat, they show us that heat exists, and is developed, under different conditions; and to expound the variety of results in the mineral world, it has been necessary to multiply yet farther the natural states of caloric (§ 448, e, 1085).

448, e. As showing farther, also (c), that there is some obscurity attending the phenomena of ordinary combustion, I may quote the

high authority, Dr. Kane, to that effect, who says, that,

"Laying aside altogether the attempt at deducing the phenomena of combustion from any change in the amount of latent or specific heat in the bodies which enter into combination, it remains only to be admitted as a general and independent principle, that chemical combination is a source of heat and light. It is, however, impossible to arrest inquiry at that point; and, accordingly, the speculations of philosophers have been directed, in seeking a cause for the phenomena of combustion, to the disengagement of electricity," &c.—Kane's Elements of Chemistry, 1841.

448, f. Now, however it may be that the results are the same in the inorganic world, upon the theories either of caloric or electricity, the remarkable differences in views in that respect show the difficulties which chemistry must encounter when it approaches the philosophy of organic heat; and this, especially, when we consider the vital nature of the development of electricity and light in living animals.—(See Medical and Physiological Commentaries, vol. i., p. 107-119.)

The physiologist undertakes no explanation of the *modus* in which organic heat is elaborated. He avoids all inquiries of that nature, although he might proceed to interrogate the manner in which the vital principle operates with as much propriety as the chemist "speculates upon the cause of the phenomena of combustion." But, in doing this, he would trespass upon inscrutable difficulties, and encumber philosophy with useless hypotheses.

8. GENERATION.

449, a. The eighth and last great function common to animals and plants is generation. This function, being alone designed for the perpetuation of the species, is not necessary to organic life. It is here, however, in all the processes that are connected with the formation of the germ, and of semen, in the preparation of the generative organs for impregnation, in the mental and physical circumstances attending the act of copulation, in the impregnation of the ovum, in the development and growth of the fœtus, in the sympathetic influences of the uterus upon the mammæ which result in the formation of milk, and in all their individual and connected designs, and in their great final cause of perpetuating the species, and in the various incidental provisions which are supplied for the fulfillment of that end, that chemistry and physics may be as effectually banished from physiology as by the demonstrations which I have made in relation to the germ, or by those which respect digestion, or organic heat, or the nervous power.—See Youth p. 376-380, § 578.

449, b. What may be the extent in which the male participates in producing the offspring it is impossible to know; probably as impossible as a knowledge of Creative Energy. We know, however, that the male and the female impress, alike, their own moral, vital, and physical character upon it. But the mother supplies the germ, also.

449, c. In another work I have examined the merits of the old doctrines of seminal animalcula, and their germinal character; lately revived along with other illusions or pretensions of the microscope. The subject is scarcely worthy a renewed discussion (§ 131).

449, d. It may be finally said, that whatever is true of the essential physiology of generation, as it relates to animals, is equally so of plants. The coincidences, too, which are so striking in this function of the two organic kingdoms, remove every ambiguity which has been supposed to attend the more important functions of plants, confirm the vital character of the whole, and, with the universal analogies, refer the whole to the same properties of life which carry on the organic functions of the animal kingdom. It were impossible, according to the ways of nature, that a function, like generation, which depends in animals upon a vital condition of all other processes, and which is a great final cause of all those processes, should, in plants, depend on others of a different nature. By the coincidences, therefore, in the function of generation between animals and plants, I prove a like coincidence in the vital character of all the organic functions of both animated kingdoms (§ 185, 1052 c).

But little can be said relative to the function of generation, beyond certain important relations that have been considered, that can serve as a ground for Institutes in Medicine (§ 63-81). Its more extended

consideration belongs to elementary works on physiology.

II. PECULIAR, OR ANIMAL FUNCTIONS.

A. Functions of Relation.

1. SENSATION.

450, a. HAVING distinguished three kinds or principal modifications of sensibility, namely, common, specific, and sympathetic, and as sensation is performed through that property, there are naturally three modifications of the function; to wit, common sensation, specific sensorics.

sation, and sympathetic sensation (§ 194-204, 1037 b).

450, b. The nerves are the organs of the functions, and the nervous centres the recipients of the transmitted impressions. But, it is important to remark, that the parts most essential to sensation are the extremities of the nerves at their origin and termination, and that the trunks are, mainly, the conductors. This is also true of voluntary motion, and of those involuntary movements that are excited by the nervous power. The nerves of the organic viscera, therefore, follow this rule, as it respects all natural, morbific, and remedial agents. A neglect of this consideration has led to fallacious conclusions in medicine from experiments on the trunks of nerves (§ 110-117, 826 d).

450, c. Common and specific sensation require a continuity of the nerves with the brain, and a co-operation of the mental power perception. Sympathetic sensation may be excited in the brain, or spinal cord, or certain parts of the ganglionic system, either in their connected state, or when disconnected. In their most natural condition it is probable that all the parts concur more or less together in giving rise to sympathetic sensation; though some parts more than others, according to the nature of the impressions transmitted and the

part from which they are transmitted (§ 201, 1037).

450, d. Common sensation appertains to all parts, and is the cause of pain. In the natural state of the body it is inappreciable, but may be greatly roused by injuries and by disease. Its intensity will then depend upon the nature of the part and the exciting cause. It is apt to be most exquisite in parts where specific sensation is least; as in

tendons, ligaments, membranous tissues, &c. (§ 198).

450, e. Specific sensation corresponds with specific sensibility. It is the function through which we acquire a knowledge of external things, and is, therefore, the great inlet of knowledge. It has, of course, the several modifications which appertain to specific sensibility (§ 199, 200); consisting, indeed, of five apparently different func-The expanded nerves of sense, which are the organs of this function, it is superfluous to say, are supplied with auxiliary means, such as the various appendages to the retina, to the auditory nerve, &c. A close analogy exists among the whole, and they may be brought more or less to the aid of each other. Although a common function, its remarkable modifications are shown by their uses, respectively, and by the necessity of certain specific stimuli to each. As with common sensation, the specific kind requires the aid of perception. The rationale of the entire function is far more wonderful and incomprehensible than that of sympathetic sensation and its various results which terminate in the influence of the nervous power on organic actions, and for which the grossest doctrines in chemistry and physics have been substituted, because the vital interpretation is "inconceivable," or cannot be subjected to the critical inspection of that far more obscure, but acknowledged, causation in the chain of perception, specific sensation (§ 222-237). What can task the understanding more than the step in the process of intellection as connected with the functions of sense; beginning with light and its properties, or with the odor which none but the dog can discern, or the abstractions that convey to the mind all the varieties in taste, or the modified undulations of air which render so distinct from each other all the gradations of sound, from the Æolian harp to the braying of a jackass; the impressions of each upon the extremities of the nerves of sense, one alone upon the eye, another alone upon the nose, and another upon the ear alone; the transmission of these impressions along the trunks of the nerves to their other extremities in the brain, and in each of the cases through the aid of some special mechanism; their excitement of the brain and the co-operation of the mind, by which the nature of the primary impression is discerned, and the external objects realized by the inward immaterial agent according to their real material existence ($\{188\frac{1}{2}, d, 500, nn\}$)?

450, f. The common hypotheses which have been propounded to explain specific sensation, such as the motion of a nervous fluid, galvanism, vibration of the nerves, the passage of light, of undulations of air, &c., to the brain, betray a general disposition to avoid the phenomena of life for those which are manifested by inanimate objects.

But, of this I have already had enough (§ 189, 234–237).

451, α . The action of material objects upon the mind through the function of sensation, and the astonishing influences of mental emotions upon irritability (§ 188, α), and of the will in acts of voluntary motion § 227, 1st, 233), bring the laws of organization and those of the immaterial mind and instinct into harmonious relation; while the

nature of mind and the impressions it receives illustrate the character of the vital properties (§ 450 c, and Medical and Physiological Com-

mentaries, vol. i., p. 92-102).

451, b. Impressions upon the brain through the medium of specific sensation leave no transcript; and perception of objects without sensation, as in reveries and dreams, has led to a denial of the materiality of the world; supported, too, by far greater ingenuity than those objections to a vital principle which are regardless of all its unique

phenomena.

451, c. It has been seen that perception is necessary to sensation, in the usual acceptation of this function, which is essentially mental. This term, however, is employed to represent the cerebro-spinal impressions which give rise to involuntary motions, whether in animal or organic life; and "feeling" is used by Mr. Hunter, and others, to denote the susceptibility of organs to the existing condition of each other, by which their concerted action is maintained through the medium of the nervous system. It is obvious, however, that the mind takes no cognizance of those impressions which result in involuntary motions; no perception, no act of the will, is excited, so far as it respects the direct results. And, although there be an analogy between all the influences of sensation in animal life, it reaches least to the movements which spring from the nervous system in organic life, since the impressions made upon the brain through specific sensation never affect the organic actions; while there is a perfect identity of effect between those impressions which give rise to involuntary movements in animal and organic life.*

451, d. As the term sensation, therefore, has a very different import in the different cases; and as in one the transmitted impressions terminate in exciting an act of the mind, while in the other no such act is called into operation; but differently, also, from the former case, the nervous power is excited in the nervous centres and then reflected with the effect of a vital agent upon all other parts (§ 226); and since, also, the impressions through specific sensation must be exerted upon the brain, while in the latter case the results may be equally pronounced whether the impressions be made exclusively upon the brain or on the spinal cord or organic nerve, I have made a third distinction in sensibility to separate its office in the function of sympathy from its province as described under the varieties of common and specific sensibility, and to avoid the confusion which has hitherto prevailed by an indiscriminate use of the term sensation (§ 194, 199½, 201, 204,

453, 523, 1037 b).

451, e. This third distinction in sensibility I have called sympathetic sensibility (§ 201); and this conducts me to a third distinction in the corresponding function, and which should be known by the same epithet (§ 464-467, 473 c, no. 5, 474, no. 4).

The epithet sympathetic denotes the special function of sympathetic sensation, which has been sufficiently described in the preceding section, and in what has been said of sympathetic sensibility (§ 201-204).

451, f. The considerations made in § 450, e, illustrate the vital philosophy of sympathetic sensation as one of the functions concerned in the transmission of impressions from one part to another through the medium of the nervous centres, and in which the nervous power is the agent by which the reflected impressions are exerted (§ 222, &c.).

^{*} If specific or common sensation affect organic actions, it is through some mental emotion which it excites. The mind is the efficient cause, p. 77-79, note.

The facts in the former case bear with the strongest force of analogy in demonstrating the entire absence of all chemical agencies in the phenomena of the nervous power. The alliance of the whole, throughout the mental and physical results of specific sensation, places the whole upon common ground in respect to principle; and if it be true that nervous agency in one case is chemical, it is equally so in all, and equally so with perception itself (§ $188\frac{1}{2}$, d). Other demonstrations to the same effect will be presented in another section (§ 500, nn).

2. SYMPATHY, OR REFLEX ACTION OF THE NERVOUS SYSTEM.

452, a. I now enter upon the consideration of a function which belongs not only to animal life, but has far greater and more important relations to the organic life of animals. Although it have no existence in the vegetable kingdom, where its anatomical medium is also wanting, it does not bestow those striking distinctions in the organic life of the two animated departments of nature which the importance of the function, and the presence of the nervous system, in the animal economy, would denote. The organic actions are essentially alike in both, conducted in both by common properties appertaining to the various tissues and organs, and only influenced in animals by reflex and direct action of the nervous power as a vital agent (§ 185).

452, b. Nevertheless, it is a function of wonderful characteristics, and can be appreciated only by an extensive investigation of its endless variety of phenomena. And yet is this function extensively ridiculed by enlightened men; and even Müller, who has written more luminously upon its laws than any other observer, applies them only in certain natural processes, considers the nervous power the actual cause of motion, construes the function of absorption according to the physical rationale, defends the hypothesis of endosmose and exosmose in extenso, interprets all the secreted products upon chemical principles, expounds diseases by the humoral pathology, and recognizes no therapeutical influences of medicine but through its absorption into the circulation. For all this he was well commended by the British and Foreign Medical Review, while the same critical survey of that remarkable work on Physiology stamped its displeasure upon those doctrines of life which render the work a proud monument of the age.

Again, no one has employed his knowledge of the laws of sympathy more usefully than Bichat. "The word," he says, "is of but little consequence, provided what it expresses is understood." And yet, while he also affirms that "we know the principle exists," he also says, that the "word is only a veil for our ignorance in respect to the

relations of the organs to each other" (§ 234).

452, c. Sympathy is the most important function which is peculiar to animals; since upon it depend, very greatly, the right performance of the organic functions, and a vast range of pathological conditions, and the greatest amount of therapeutical influences. It also overthrows the venerable doctrines in humoralism, in all their contemplations of vitiated blood, morbid lentor, "living putrefaction," and of those conformable therapeutical means which were invented under the significant names of incisives, deobstruents, inviscants, incrassants, diluents, attenuants, astringents, relaxants, refrigerants, &c.

453. Sympathy has been commonly reputed as one of the properties peculiar to animals; but it is not only a function, but one of great

complexity, since it involves the united operation of sensibility and the nervous power. The result of that concerted action is sympathy, or reflex nervous action. This is the established acceptation; but the nervous influence often operates through motor nerves alone, as in mental and physical excitements of the nervous centres; and hence, in part, my preservation of the generic term sympathy (§ 638½).

In the farther prosecution of this subject, I shall consider,

I. The general uses of the nervous systems. II. The different orders of nerves (§ 462, &c.).

III. Exp. to determine the Laws of the Vital Functions (§ 476, &c.).

IV. The varieties or kinds of sympathy (§ 495, &c.).

V. The laws of sympathy, and their application to pathology and therapeutics; the latter being peculiar to myself (p. 912).

I. OF THE GENERAL USES OF THE NERVOUS SYSTEMS.

454, a. The phenomena of the nervous systems (the cerebro-spinal and ganglionic), in their connection with organic processes, forcibly declare how broad is the gulf between the properties and laws of dead and living beings, and how vast, magnificent, and profound is the science of life in its varied aspects of health and disease.

454, b. The nervous system having no existence in plants has given rise to the fundamental distinction of "animal and organic life" (§ 96-

123), although in animals it belongs to both lives.

454, c. The cerebro-spinal system appertains particularly to the organs of animal life, though it contributes largely to the organic viscera (§ 111–117, 224, 233 $\frac{4}{5}$, 356 a, 409 k, 461, 478 b, 488 $\frac{1}{2}$, 493 cc, 647 $\frac{1}{2}$, 893 $\frac{1}{2}$).

The ganglionic system is universally appropriated to the organs of organic life, and pervades every part of the animal; since organic actions are carried on as well in the organs of animal life as in the organ-

ic viscera, and require the influences of this system (§ 115).

455, a. The great final cause of the brain is to subserve the intellectual powers in man, and instinct in the lower animals (§ 241, 454 b, 500 p). But reason and instinct would avail but little were their opcrations circumscribed by the limits of their organ. Hence the brain is prolonged into nerves, and various connections are thus established with all parts of the body, and with the external world. Admirable as is this Design of associating in harmonious action the immaterial with the material parts, it would still be defective, and the economy of nature obviously violated, were not an organ so prominent in the animal mechanism rendered subservient to the great purposes on which its existence depends. Therefore that other system, the ganglionic, has been established, with intimate connections with the cerebro-spinal, through which they co-operate together, especially after independent life begins. Nevertheless, the essential influences in organic life devolve mostly upon the ganglionic system, whose principal offices, besides that of combining the organic functions (§ 113), consist in so modifying the functions as to variously affect the secretions in their quantity and quality (the organic in their vital constitution), and in supplying the stimulus of nervous influence to the muscular tissue in organic life (§ 224, 356 a, 422, 461, $461\frac{1}{2}$, 473 c, $475\frac{1}{2}$, 483 c, $488\frac{1}{2}$, 500 g, m, 524 d, no. 7, 889 g, $892\frac{3}{4}$, 893 a, c, $893\frac{1}{2}$, 902 g).

455, b. It appears, therefore, that one of the great secondary uses of the cerebral system is that of co-operating with the ganglionic in

establishing a circle of sympathies among the organs of organic life and preserving the whole in that harmony of action that is indispensa-

ble to the life of complex animals.

455, c. Thus we learn that the various parts of the organic mechanism of animals are not only indispensable to each other, but that a certain established influence of one upon the other is necessary to each, and that the functions of the whole may be fatally deranged, either directly, by causes that may interrupt the common chain by which the relations are established, or indirectly, as by a blow on the stomach, or by poisons acting upon some part of the intestinal mucous tissue, or by withdrawing some particular organ from the symmetrical whole

(§ 109, 129).

455, d. Whatever, indeed, may affect the powers and embarrass the functions of the cerebro-spinal system, will more or less disturb this concert of action, may modify the functions of every part, and may derange the whole series of vital phenomena. The nature of the disturbances will depend entirely upon the nature of the impressions produced upon the nervous systems, as well as upon the rapidity and violence with which the impressions are made. Direct injuries do it in one way, and according to their nature and extent. Morbific, or other causes, acting upon other parts, affect the nervous centres, and consequently give rise to remote derangements, in other ways, according to their nature, and the violence with which they operate. Medicines do the same thing, and according to their nature, their dose, and according to the nature of the part, as well as the existing state of the part to which they are applied, or that of other parts upon which they may act sympathetically. Intricate reflex nervous actions, in all these cases, are liable to spring up, and that, too, in rapid succession (§ 222- $233\frac{3}{4}$, &c.).

455, e. The same laws, precisely, are concerned throughout. We do not, however, witness the display of reflex nervous actions in health as in disease, or as when remedial agents operate; since, in the natural state of the body, the nervous influence is more or less in equilibrio; operating uniformly and equally on all the organic viscera, and thus maintaining among them one concerted, harmonious action. But this power being constituted with the greatest sensitiveness to the various conditions of all parts, that it may transmit the existing condition of each one to the whole (as strikingly seen in the almost instant interchange of function between the kidneys and skin, on the contact of cold air, &c., § 422), it necessarily happens that when the state of any one part is varied from its natural standard, that part will transmit an unnatural influence to the brain and spinal cord, will develop the nervous power in an unnatural manner, and thus produce disturbances in other parts (§ 350, no. 19). The alterative influences, therefore, of morbific and remedial agents necessarily result from the natural physiological laws of the nervous system in connection with the instability of the organic properties, nor can it be otherwise. The principle is absolutely ingrafted upon the constitution of animals.

455, f. I say, therefore, that when unusual causes operate, whether upon the nervous centres or upon remote parts, they necessarily develop the nervous power in greater intensity than it exists in health; when it is reflected abroad upon various organs, and with the greatest variety of effect. The parts upon which it may fall will depend upon

their existing susceptibility and the nature of the remote causes; and the nature of the effects produced will depend greatly upon the particular virtues of the morbific or remedial agents; for it is also an important law that the nervous power itself will be altered according to the particular nature of the impression which may be produced upon the part on which the agent may exert its direct effect (§ 222, &c.).

455, g. The actions which are thus influenced through the connecting medium of the nerves are not alone the great general functions of organs, such as digestion, the action of the heart, &c., but, also, those of their minute constitutional organization. Here it is, indeed, that morbific and remedial agents exert their principal effects (§ 483, &c.).

456, a. In the ordinary rhythm of the organic system, however, the capillary and extreme vessels are not as dependent on the nervous influence for the precision of their functions, as the complex organs (§ 455, e). It is greatly with these vessels as with the analogous ones in plants. They have an independent function in each particular part, the performance of which does not require so much a harmonizing nervous influence as in the collective sense. Herein also is seen a reason of the absence of a nervous system in plants, while it is more or less necessary to animals. The vessels go up continuously from the roots to the leaves, and continuously back again, and there are only vessels; no complex organs. Each part of a plant has within itself an organization adequate, or nearly so, to its independent existence. It is otherwise, however, with animals. Here, other essential parts are superadded to the simpler mechanism, are made dependent on each other, and a certain correspondence of action rendered necessary to the integrity of the whole. For the fulfillment of these ends the nervous system is also superadded, with its wonderful attribute, the nervous power, that a perpetual change of influences shall be maintained among the great organic viscera, while it is also made instrumental in exciting and modifying the organic functions of every part, and thus also affecting the nature of the products (\$ 226, 232, 399, 446 a, 461, 473 c, 483 c, 485, 489, 512, 746 c, 846, 889 g, 902, 952).

456, b. Hence it is that slight influences upon the nervous centres will determine the nervous power, with a very manifest effect, upon the capillary and extreme vessels, as seen in blushing, and in the experiments by Philip (§ 227, 477, &c.); and coming to the ordinary operation of disease, and of morbific and remedial agents, we have constant demonstrations of the great susceptibility of these vessels to the action of the nervous power, and of strong reciprocal sympathies among them, and of consequent changes in the products (§ 394, 1040).

457. One of the most striking peculiarities of the ganglionic system is that of its not transmitting the influences of the will to the organs which it supplies, notwithstanding it is so intimately combined with the cerebro-spinal nerves; while, on the other hand, the passions operate more powerfully through the ganglionic than through the cerebro-spinal nerves (§ 476 c, 500 e).

This fact shows us at once that the sympathetic system must have certain special functions; and when we trace out its anatomical constitution, and its distribution to the essential parts of organic life, we perceive that one special office must be that of maintaining a harmony of actions among these parts; and experimental observation confirms this induction. Consequently, from the exquisitely delicate nature of

this high office the nerve is rendered intensely susceptible, and from the intimate manner in which it pervades the organic tissues it is made to exercise a profound and somewhat governing influence upon

their organic actions (§ 456 b, 1040).

458. The relations of the cerebro-spinal and ganglionic systems to each other, their special or mutual functions, and those of individual nerves, all having their distinct individuality, yet all more or less related and concurring in harmony, and for important purposes in animal and organic life, supply the most complex and astonishing in stances of Design to be found in nature; and their natural attributes, existing under the most absolute laws, afford a ready interpretation of the endless phenomena of reflex actions, as the result of disease, or of morbific or remedial agents.

459, a. All parts of the nervous centres are not only more or less mutually connected in function, but all parts of the nervous system are subordinate to the brain. There are no distinct, separate, and independent influences, of an involuntary nature, exerted by any parts of the nervous centres in their state of integrity. They all concur more or less together. This is experimentally demonstrable, as well as denoted by the natural phenomena. If, therefore, it should appear from experiments upon the spinal cord, for example, while connected with the brain, through any remaining communications, that the influences are determined by the cord alone, we may be assured that the brain has participated (§ 201, 473, 481, Exp. 15).

459, b. I have said in my Essay on Bloodletting (in Med. and Phys. Comm.), that the injuries which are inflicted on the spinal cord, to determine the specific functions which have been assigned to it, are so severely propagated to the brain, and may so affect the properties of that organ, that the results which appear to flow from the spinal cord may be actually due to the cerebral influence, or to an interruption of that influence when the spinal cord is divided or destroyed. Both principles, in the latter case, may act in co-operation; the cerebral influence being determined through the superior nerves and the ganglionic system, and otherwise impressed by a reflected influence from below that part of the spinal cord, where its direct connection with the brain is interrupted (§ 481, Exp. 12, 15).

While, therefore, the brain remains, experiments upon the spinal cord are entitled to much less confidence than those which are made upon the brain. But even when the brain is removed, the vital properties of all parts become so profoundly modified in consequence, that we can scarcely infer with accuracy the specific functions of the spinal

cord from subsequent experiments (§ 477, &c.).

459, c. The late experiments by Dr. Stilling, with strychnia applied to the spinal cord, are entirely consistent in their results with the foregoing remarks (b). From these experiments he supposes that the spinal cord is greatly independent of the brain, and that when divided in numerous places, each portion is capable of the same influences upon the parts it may supply, as when the whole cord is in its natural state. Thus, when the small portion connected with the fore-legs is separated from the rest of the cord by two incisions, and strychnia is applied to this isolated part, the legs will be convulsed. Still, however, there are remaining and important communications of this apparently isolated part with the head, and with all other parts of tho

spinal cord, which will forever embarrass these critical inquiries, unless there be a removal of the brain (§ 473 a, no. 2, 473 c, 494 d, 514 e).

459, d. "The experiments of M. Le Gallois," says Wilson Philip, "prove, in the most satisfactory manner, that a principal function of the spinal marrow is to excite the muscles of voluntary motion, and that it can perform this office independently of the brain, as after the removal of the brain. Yet we constantly see injuries of the brain impairing the functions of the spinal marrow. Of this apparent inconsistency, M. Le Gallois justly remarks, that two facts, well ascertained, however inconsistent they may seem, do not overturn each other, but only prove the imperfection of our knowledge."

Now, in the foregoing case, there is no difficulty in reconciling the facts by the interpretation which I have given to the action of the will and of the nervous power. The will operates as an exciting cause to the nervous power, which then determines voluntary motion. But, the motions are never voluntary after the removal of the brain; but the nervous power pervades the whole system of motor nerves, and when stimuli are applied to the spinal cord after removing the brain, the nervous power becomes an exciting cause of involuntary motions

(§ 226, 473, 500).

459, e. Every principal part of the nervous system has a certain special office which is exercised in conjunction with the whole. "The cerebrum does not act like the cerebellum, nor the cerebellum like the medulla oblongata, nor the medulla oblongata like the spinal cord and nerves. In the cerebral lobes resides the faculty by which the animal thinks, wills, recollects, judges, becomes conscious of sensations, and commands its movements. From the cerebellum is derived the faculty which co-ordinates the movements of locomotion; from the tubercula bigemina or quadrigemina, the primordial principle of the action of the optic nerve and retina; from the medulla oblongata, the motor or exciting principle of the respiratory movements; and, lastly, from the spinal cord, itself, the faculty of blending or associating into combined movements the partial contractions immediately excited by the nerves in the muscles of animal life."

459, f. Enough, however, is known to show us, that when the cerebro-spinal and sympathetic systems exist as a whole and unimpaired, they act more or less as a whole; but that different parts have certain peculiarities of function, and that when injuries befall any part of these great systems, a portion of the whole may perform certain circumscribed functions, at least for a limited time, and often, perhaps, as perfectly as the whole apparatus in its state of integrity (§ 201,

515, 516 d, no. 8).

Impressions, as I have said, when transmitted through sympathetic sensibility, may be received either by the brain, spinal cord, or certain parts of the ganglionic system; and either connectedly or independently. But, in the natural state of the nervous system, all such impressions, when received especially by an individual part, are doubtless propagated to the other parts, and institute that harmonious concurrence in all the parts which renders the whole nervous system instrumental in determining the ultimate phenomena. This is even true of so local a phenomenon as the contraction of the sphincter muscles, however that contraction may be maintained after destruction of the brain and of the superior parts of the spinal cord (§ 461½, a). These

conclusions are warranted in experiment, and by all that is known of the dependence of the harmonious relations of organs upon the presiding influence of the nervous system. There must be harmony there as a fundamental requisite (§ 129).

459, g. In the application which I have made of the nervous power, in the present and in my former works, to the theory of disease and to the modus operandi of remedial agents, it is important to regard the whole nervous system in its unimpaired relations to its own and to

other parts.

460. No experiments upon the sympathetic nerve can show that it is more than tributary to the organic processes; for the moment any unusual impressions are made upon it, the nervous influence is unnaturally excited, and determined with more or less violence upon the or-

ganic properties, and thus deranges the functions.

461. It is an assumption to say that the nerves are the generating sources of the secreted products, however certain it may be that they influence the organic processes and their results. If the products are altered by impressions made upon the brain or nerves, it is because the nervous influence is preternaturally determined, as a morbific agent, upon the organic viscera, and because the nervous influence exerts naturally a modifying effect upon the products of organic actions. division of the pneumogastric or of any other nerve may have all the effect of a morbific agent, producing congestion and inflammation; the very division of the nerve determining a shock of the nervous power upon the organic properties of the part to which the nerve is distributed. But, in the instance of dividing the pneumogastric nerve the gastric juice and the pulmonary mucus are secreted in preternatural abundance. Digestion, however, becomes at once greatly impaired; but even that may be more or less restored by rousing the nervous influence in the divided portion of nerve leading to the stomach by means of galvanism, or other irritants applied to the nerve, thus perfecting the juice (§ 226, 409 k, 446 a, c, 489, 493 cc).

 $461\frac{1}{2}$, a. The brain and spinal cord are not necessary to the organic life of the fœtus, not even to the action of the sphincter muscles; since both have been wanting in the full-grown human fœtus (§ 459 f). In the fœtal case reported by Dr. Clark in the London *Philosophical Transactions* (1793, p. 154), in which it is said that there was no trace of nerves, it cannot be doubted that the sympathetic existed, since the laws in respect to the organic compounds of animals are as applicable to such a monster as to the perfect being, and since also these compounds in the latter case are imbued with special vital conditions through influences of the sympathetic nerve upon the secreting vessels. The sphincter ani, the heart, &c. require the stimulus; but there was no anus in the above case (§ 409 k, 473 c, 483 c, $488 \frac{1}{5}$, 493 c, d).

 $461\frac{1}{2}$, b. Hence it appears that the sympathetic nerve is, to a certain extent, independent of the brain and spinal cord, and the relations of the latter to the former become most important after independent life

begins (§ 224, 473 c, 483 c).

 $461\frac{1}{2}$, c. In brief, then, the influences of the cerebro-spinal and sympathetic systems are more or less reciprocal in organic life. And, although sympathies may be combined by the ganglia of the sympathetic nerve, as in contiguous sympathy (§ 497), this nerve transmits the impressions it receives to the brain and spinal cord in the same

way as the cerebral and spinal nerves, and influences are propagated from the cerebro-spinal axis upon either system of nerves, and the organs they supply, in a like manner (§ 111-117, 227-230, 455, 893).

II. OF THE DIFFERENT ORDERS OF NERVES.

462. Corresponding with the two important functions of the brain and spinal cord, those of receiving impressions from external objects, and of generating the nervous power, are two orders of nerves; whose distinct characteristics were first pointed out by Sir Charles Bell. It is the office of one of these orders of nerves to transmit the impressions to the nervous centres, and of the other to serve as a medium for the exercise of the nervous power upon all parts of the body. This combined function establishes the more complex one of

sympathy, or reflex nervous action.

463, a. The foregoing anatomical discovery only establishes what was before known of the laws of sympathy by accurate observers of nature. The general attributes of sympathy were understood by Hippocrates, and were at the foundation of no small part of his medical philosophy and practical habits. From the origin of medicine to the present time the subject has engaged the attention of the medical world. Its important outlines were originally drawn from the vital phenomena alone. We learn from Plato, a cotemporary of Hippocrates, that the general doctrine of sympathy, in its application to the cure of disease, was considered fundamental by physicians. Thus: "Occulorum morbosos affectus sanari non posse, nisi prius curetur caput, neque caput nisi prius curetur corpus, neque corpus sine animo, aiebat medicus quidem apud Platonem." Galen writes of it.

463, b. When the nervous system became understood, this knowledge aided greatly an analysis of the laws of sympathy. "Glisson, in 1677, speaks of an influence being 'reflected' from one nerve at its origin upon other nerves, so as to cause consensual movements." Unzer, in 1771, was close upon Bell's discovery, and Whytt and Monro also carried on the inquiry in conformity with the designs of structure. In 1784, Prochasca established the theory of reflex action of the nervous system. This great theory has been recently analyzed and reduced to a system of magnificent laws by Professor Müller, to which Dr. Hall and others have also made some contributions.

464. But, the present century contributes to medicine a discovery which lays open the precise mechanism that subserves the laws of sympathy. It consists, essentially, in having demonstrated the two orders of nerves (§ 462). With this mechanism, in its connection with the phenomena of sympathy, we move forward with unerring certainty to the exposition of principles and laws which are as peculiar to organic beings as their structure and results, and as determinate

as the mechanism is replete with consummate Design.

465. The posterior roots of the spinal nerves, which have a ganglion upon them, denote the part appropriated to sensation, or to such impressions as may be transmitted from the periphery to the centre. The anterior roots, which are without a ganglion, exercise the motor function, and that range of influences upon which all the immediate and important results of sympathy depend (§ 226, &c.). The fibres of these roots are gathered into bundles, forming the nerves, and are thus distributed to various well-known parts; and what is of the high

est moment in organic life, and mainly important to the purposes of these Institutes, these nerves contribute to the great sympathetic (§ 111–117, 129, 500 e-m, 514 c, d, 515, 520, 891 $\frac{1}{2}$ g, k, 893 a, c, 1037 b).

466. The motor and sensitive fibres of a common nerve do not unite, but are even distributed separately in the organs which they supply.* They have, therefore, no action upon each other except through the nervous centres. The phenomena, at least, declare it.

467. All the late anatomical investigations of the spinal cord by Stilling, Van Deen, Budge, and others, go to confirm the foregoing conclusions (§ 465, 466). They have also probably indicated the anatomical mediums, in the spinal cord, by which impressions are conducted to the brain, and influences transmitted from that organ. Stilling, for instance, supposes that the longitudinal fibres of the posterior gray substance of the cord transmit the sensitive impressions to the brain, and that the longitudinal fibres of the anterior gray substance are the medium through which the will operates in voluntary motion.—See § 1037 b.

468. The foregoing discovery has led to the knowledge that one of the functions of a nerve may be destroyed without impairing the other. If the posterior root be paralyzed or divided, sensation is destroyed, but not the power of motion. So, on the other hand, if the anterior root be divided or paralyzed, voluntary motion is destroyed, but not sensation; and, as organic motion is independent of the will, it is only influenced, not destroyed, by this injury of nerves (§ 205–208,

226, 257, 500).—See later observations, § 1037 b.

469. The two orders of nerves occur in the great sympathetic, and appertain, also, to those nerves which proceed directly from the brain, where they are either compounded, as in the spinal nerves, or make up, respectively, distinct nerves of sensation and motion.

Those which proceed from the brain are distributed into three

classes:

1st. "Nerves of special sense; namely, the olfactory, optic, and

auditory nerves.

2d. "Mixed nerves with the double roots; the trigeminus, glosso-pharyngeus, (?) and the par vagum with its accessory, and, in several

mammalia, the hypoglossus.

3d. "Single-rooted nerves, for the most part of motor function, which are either themselves entirely motor, and receive sensitive fibres from other nerves, or which, if their roots contain sensitive fibres, still cannot be classed with the double-rooted nerves. These are the occulo-motorius, the trochlearis, the abducens, and the facial nerve."—MÜLLER.

470. The nerves of the sympathetic system are exquisitely endowed with that modification of sensibility which I have denominated sympathetic sensibility (§ 201–203, 451, &c.). This modification is not less strongly pronounced in the sympathetic system than specific sensibility in the nerves appropriated to the organs of sense; for it is through this medium that all the organic viscera "feel," as it were, the condition of each other.

The nerves of the ganglionic system have only an involuntary mo-

tor influence upon the parts to which they are distributed.

"It being shown that the sympathetic regularly receives fasciculi of motor and sensitive fibres from the spinal nerves, as their motor

^{*} This is inferable from the phenomena, and from these the laws are deduced (\$\dagger\$ 131, 990\frac{1}{2} c).

and sensitive roots, the existence of a similar relation between it and those cerebral nerves which are analogous to the spinal nerves, in having double roots, becomes very probable."—MÜLLER.

Laws of the Action of Motor Nerves of the Cerebro-spinal System.

471. 1. "The motor influence is propagated only in the direction of the nervous fibres going to the muscles, or in the direction of the ramification of the nerve; and never in a retrograde course."

2. "The application of mechanical or galvanic irritation to a part of the fibres of a nerve does not affect the motor power of the whole trunk of the nerve, but only of the insulated portion to which the

stimulus is applied."

3. "A spinal nerve entering a plexus, and contributing with other nerves to the formation of a great nervous trunk, does not impart its motor power to the whole trunk, but only to the fibres which form its continuation in the branches of that trunk,"—MÜLLER.

Laws of the Action of Sensitive Nerves of the Cerebro-spinal System.

472. 1. "When the trunk of a nerve is irritated, the sensation is felt in all the parts which receive branches from it. The effect is the same as if all the ultimate ramuscules had been irritated."

2. "The sensation produced by irritation of a branch of a nerve is confined to the part to which the branch is distributed, and generally, at least, does not affect the branches which come off from the nerve

higher up, or from the same plexus."

3. "When, in a part of the body which receives two nerves of similar function, one is paralyzed, the other is inadequate to maintain the sensibility of the entire part. On the contrary, the extent to which the sensibility is preserved corresponds to the number of the primitive fibres unaffected by the lesion."

4. "When different parts of the thickness of the same nerve are separately subjected to irritation, the same sensations are produced as if the different terminal branches of these parts of the nerve had been irritated." The sensations, however, are greatly less in the for-

mer instance (\S 826, d).

5. "The sensations excited in the minute elementary fibres are transmitted from the surface of the brain, without being communicated to the other fibrils of the same nervous trunk."—MÜLLER.

The foregoing laws are relative to specific sensations, and are more or less applicable to sympathetic sensation (§ 450, 451).

Of the Spinal Cord.

473, a. 1. "In a physiological point of view, the spinal cord so far agrees with the nerves that it propagates actions of the nerves, which enter it, to the brain, just as the cerebral nerves communicate impressions made on them immediately to the sensorium commune; and that it communicates the influence of the brain to the nerves arising from it, which thus receive, through the medium of it, the cerebral influence, just as if they arose from the brain itself. In other respects, however, the spinal cord differs essentially from the nerves in possessing properties which belong to it as a part of the central organs, and do not reside in the nerves (§ 459).

2. "All the cerebral nerves are immediately subject to the influence of the brain, and all the spinal nerves are subjected to the same influence through the medium of the spinal cord. As soon as the transmission of this influence is interrupted, impressions on sensitive nerves cease to be propagated to the sensorium, and the brain loses the power of voluntarily exciting the motor action of the nerves which are withdrawn from its influence. When the communication of the brain and spinal cord with the nerves is interrupted by wounds, pressure, or paralysis, all the branches which are given off below the affected spot cease to be voluntarily excited by the motor action; and the action of external stimuli on the same parts produces no sensation.

473, b. "Those branches, on the contrary, which come off from the nerve above the point of injury are still subject to the influence of the brain and of volition, and, when irritated, give rise to sensation."

473, c. "The parts of a nerve below the injured point preserve, however, their motor power for a certain time. It is merely the influence of the brain upon them that is lost. The nerve does not lose its excitability to external agents until it has been several months cut off

from intercourse with the brain" (§ 459 c, 461).

In organic life impressions may still be propagated to and from the brain upon parts situated below the point of interruption, through the sympathetic nerve, and although there be no other medium of communication than by the connection of the sympathetic nerve with the blood-vessels. This is an important consideration in forming conclusions from certain experiments upon the nerves, with a view, in part, to ascertain the modus operandi of morbific and remedial agents in their action upon organs distinct from each other.

3. "In man and the higher animals the spinal cord stands in the same relation as all the cerebral nerves to the brain. It is to be regarded as the common trunk of the nerves of the body; although it is,

besides this, distinguished by special properties."

4. "The fibres of the spinal cord pass through the medulla oblongata to reach the sensorium commune. All the primitive fibres of the nerves terminate in the brain; those of the cerebral nerves immediately, those of the spinal nerves through the medium of the spinal

5. "The spinal cord has the property of reflecting irritations of its sensitive nerves upon the motor nerves, but without itself perceiving the sensation" (§ 201-204, 451 d-451 f, 1037 b).

"The spinal cord, even when separated from the brain, and without

any external stimulus, can excite automatic movements."

6. "The spinal cord, although capable of exciting the motor nerves to automatic actions, nevertheless, in the healthy state, leaves a great part of the motor nerves, those supplying the muscles of locomotion more especially, in a quiescent state; while on others it exerts a constant motor influence (§ 500, k). It thus maintains constant involuntary contractions, which are arrested only by the spinal cord becoming paralyzed. The motions of this kind are, 1st, those of muscles which are also subject to the influence of the will, as the sphincter ani; 2d, those of muscles not subject to the influence of the will, as the sphincter vesicæ urinariæ, the muscular coat of the intestines, &c."-MULLER. Those muscles may be affected by the will (§ 500 e). 474. 1. "The activity of all the special functions of the nerves is

determined by the central organs, partly under the influence of the mind, and partly independently of this influence."

2. "The central organs connect all the nerves into one system. To

this even the sympathetic nerves do not form an exception."

3. "The central organs are the exciters of the motor nerves which conduct the motor influence of the nervous principle to the muscles. This motor influence may be constant, as we see in the case of the sphincters; secondly, it may be evidenced in intermittent rhythmic movements, such as those of respiration; and, thirdly, the motor influence may issue voluntarily from the sensorium commune (the part of the brain on which the mind acts) to the central organs; this sensorium commune being subject to the spontaneous actions of the mind.

"The motor nerves are affected by this motor influence in two ways." First, the nerves of one class act as mere conductors of it. In their normal state they do not exert this power spontaneously, but only when excited by the central organs. These are the motor nerves of the ce-

rebro-spinal system.

"Secondly, the nerves of the other class, which are quite withdrawn from the influence of the sensorium commune, as far as regards voluntary actions [not the passions], are likewise capable of being excited to constant and periodical action by the central organs. But they present the peculiarity of affording independent discharges of the nervous influence; although, after a time, communication with the central organs is found to be necessary for the production of the nervous power. Such are the sympathetic nerves with regard to their motor actions."

The first of the foregoing varieties of motor influence is the exciting cause of voluntary motion. By the second I interpret, mostly, the operation of morbific and remedial agents upon parts not immediately connected with the direct seat of their action, and the phenomena of sympathetic diseases, and other sympathetic results among separate

parts.—See Rights of Authors p. 912.

The former part of the next following law, and § 473 c, no. 5, have led me to distinguish the third kind of sensibility and sensation, which

I have denominated sympathetic (§ 201-204, 451). Thus:

4. "Impressions conveyed by the sensitive nerves to the central organs are either reflected by them upon the origin of the motor nerves, without giving rise to true sensations, or are conducted to the sensorium, the seat of consciousness."

5. "The nervous influence is generated in the central organs." This is not universally true, since " The maintenance of the excitability in the nerves does not, however, depend solely on the continuance of the influence of the central organs on them, but also upon their own activity."—MÜLLER.

It is still a problem whether the "activity" of the nerves here spoken of be not equivalent to a partial production of the nervous power. There are many facts which appear to denote a low degree of this

office (§ 224, 461, 497).

475. It remains now to say, under the present section, that it is important that the hypothetical words motor and sensitive, and senso-motory, do not betray us into the belief that the nerves are the causes of motion, or that there is any sensation connected with the organic phenomena of sympathy (§ 201-215, 257, 222-233, 451). The term "cxcito-motory" is far preferable to motor; and sensitive it might be difficult to improve The term reflex involves profound philosophy.

 $475\frac{1}{2}$. Although the nervous power is the only immediate exciting cause of voluntary motion (§ 258), the mind is a remoter cause (and therefore a substantive agent), and so far voluntary motion is on common ground with motions in organic life, where, for example, the blood is the remote exciting cause for the heart and blood-vessels, food for the intestine, acting upon their lining tissues (§ 136), while the nervous power, by reflected action, is the stimulus for the muscular tissue in natural states. But all muscles may be made to act by other stimuli (§ 243-246, 476 c, 498 e, 500 m, o, 514 f, $647\frac{1}{2}$, 1042).—Note A.

III. EXPERIMENTS TO DETERMINE THE LAWS OF THE VITAL FUNC-

1st. On the Principle on which the Action of the Heart and Vessels of Circulation depend.

476, a. I now come to certain important experiments by different observers, especially by Dr. A. P. Wilson Philip, as contained in his work on the Laws of the Vital Functions. It was the main object of those experiments to demonstrate the independence of organic functions of the nervous system; to show that those functions arise from the organic properties (§ 183, &c.); and they are perfectly triumphant. They have been often repeated, and their results as often verified. It may, therefore, be thought that a simple reference to those results would answer the objects of the present work. But, an age of materialism requires a constant appeal to the senses, as the only recognized mode of reaching the understanding (§ 234, $350\frac{3}{4}$ k); and, I have in view not only the great original objects of those experiments, but what is still more practically important, and peculiar to myself, the application of the laws of the nervous system which they illustrate to the operation of morbific and remedial agents, having especially employed them for the last purpose to demonstrate the philosophy of the operation of less of blood, in the Medical and Physiological Commentaries, vol. i., p. 161-173, &c. The experiments show us how it is that morbific or remedial agents, when applied to a part, may develop and modify the nervous power, and reflect it with various effect upon other parts (§ 226). They also place all the processes of living beings upon purely vital grounds; even the vegetable kingdom, by the force of an incontrovertible analogy (§ 1041.—Also, Rights of Authors).

476, b. Prior to the time of Haller, the nervous power was considered, in one way or another, as indispensable to the motions of the heart, and the brain was the seat to which the power was referred. Whytt had just before laid the foundation for rejecting the supposed necessity of the nervous system to organic life. Haller then took up the inquiry, and carried it forward by a multitude of experiments, and overthrew the doctrine of the necessity of the nervous system to organic actions (§ 167). The experiments of Philip confirm those of Haller, while, also, they are more conclusive. But he is entitled to the greater credit of demonstrating, experimentally, that organic actions are influenced by the nervous power, although it was clearly known to Whytt, Haller, and Prochasca, that such an influence obtains; while Haller, like Philip, separates it entirely from the natural relations of the nervous system to the organic functions. Prochasca, also, had ascertained, near the close of the last century, about ail that is now more distinctly known of the doctrine of reflex nervous

action, or remote sympathy; but the nature of the principle, and the remarkable distinction in the constitution of the anatomical medium, were not shown till demonstrated by the experiments of Bell and Philip (§ 462-469). Hunter, reasoning upon the natural phenomena of healthy and morbid conditions, contributed largely to the inquiry. Bichat followed immediately after, and pointed out the natural distinction of the two lives, analyzed the tissues (§ 86-88, 96-101), and developed, more than his predecessors, the nature of the vital properties, and construed all the phenomena of life, healthy and morbid, by

the normal and abnormal states of the properties of life.

476, c. It has been a question of difficult solution, how the passions should affect so sensibly the actions of the heart, while the will has no influence upon this organ. And so of all other organic viscera. This problem I have explained by showing that the will is a distinct element of the mind, as the passions are equally distinct. One determines the nervous power upon the voluntary organs, the other upon the involuntary; each having their great, specific, final causes (§ $188\frac{1}{2}$ d, 205-208, 226, 233, 481 b, 486, 487, h, 492, no. 7, 500 d-k, 951). In the latter respect, the passions are exactly analogous to the influence of morbific or other foreign agents that may operate either directly or indirectly upon the brain; being, like those agents, capable of modifying the nervous influence in its relation to the actions of organic life, while the will is incapable of such modifying effect upon the nervous influence in its relation to the actions of animal life (§ 226-228, 233, 500 d-k). The principle depends greatly upon the fact that the will limits the nervous influence to cerebro-spinal nerves (except § 500 dd, e), while mental emotions act

chiefly through the sympathetic (§ 500 g, 893 a, c, 893 $\frac{1}{2}$, 1067, 1072 b). 476 $\frac{1}{2}$, a. The researches of Le Gallois upon the influence of the medulla oblongata and the spinal cord on organic actions led immediately to those by Wilson Philip, and others who embarked in the same inquiry. Le Gallois very happily analyzed the relations of the medulla oblongata to the respiratory function, and the various movements of the process, and showed that it was the most mortal part of the body, by its immediate control over that function. The subsequent discoveries of Sir Charles Bell as to the sensitive and motor nerves have shown, also, that it is in the medulla oblongata that the

nervous respiratory influences have their centre.

476½, b. Le Gallois' experiments upon the spinal cord, and his inductions from them, and as sanctioned by others, are remarkable exemplifications of the fallacies to which results, artificially obtained, may conduct us, and supply a forcible illustration of the propensity of the mind to grasp at a single fact, and to draw important conclusions from it, to the exclusion of all others, however contradictory. It is mainly, however, as to the supposed dependence of the functions of the heart, intestines, and other organic viscera, upon the spinal cord, that these errors relate. A general summary of the observations will aid the inquirer after the philosophy of this subject. I am the more induced to present this outline from the misapprehensions which continue to surround the subject, even in the ranks of the most erudite physiologists. Thus, Dr. Marshall Hall, in his late Memoir on the Nervous System (1841), inculcates the following doctrines: "The spinal marrow," says Dr. Hall, "exclusive of the cerebrum, is the source

of animal life."—" The IRRITABILITY of the muscles of organic life depends, probably, on the ganglionic system" (§ 188-193. Also, my Essay on the Modus Operandi of Remedies, p. 42, in Med. and Phys.

Comm., vol. iii.).—§ 1041.

476½, c. Such were the results of the experiments, and such their novelty, that, having led their author to the conclusion that the functions of the heart, and other organic viscera, depend upon the nervous power of the spinal cord, the doctrine was received with éclat by the French Institute, and, indeed, by all Europe, in defiance of the well-known fact that fœtuses have been born alive without brain and spinal cord, that the heart will palpitate for hours after its removal from the body, that the intestines will roll about upon the table, when air and injuries, not the nervous power, are exciting causes. They simply took, as the ground of their conclusion, the safety of excision of the brain, or of its removal from the cranium, contrasted with the destructive effects of crushing the spinal cord (§ 456, 461½ a, 490, 498 e).

476½, d. The foregoing conclusion was inferred from the interruption of circulation by destroying the spinal cord by a wire thrust down the spinal column. The action of the heart, however, was not wholly arrested; but it failed to circulate the blood in the large arteries. This was supposed to be owing to a privation of the nervous power, by which the heart became enfeebled. Le Gallois also supposed that the actions of the heart were irregularly performed, which was also

an error.

Next, he destroyed only small portions of the spinal cord, and the results led to the conclusion that it is not from the whole spinal cord that every part of the body derives its organic life, but from that part of it only from which the nerves are supplied. And, although this philosophy is wrong, the conclusion is right, that in destroying any particular part of the spinal cord, we only impair life in those parts of the body which correspond to that part (§ 507–510).

 $476\frac{1}{2}$, c. Now, although rabbits twenty-two days old have no difficulty in living for some time after the head is cut off, yet the fact was ascertained that the destruction only of the spinal cord destroyed life, at that age, in less than four minutes; respiration ceasing first. This experiment, especially, led to the belief that the principle of life upon

which the heart depends resides in the spinal cord.

Le Gallois next ascertained that the destruction of either the dorsal or cervical portion of the spinal cord was fatal to rabbits of the foregoing age, even in a shorter time than that of the lumbar portion; that is, in about two minutes. The results, however, as to time, varied at different ages; and death took place soonest in parts that were

opposite to the portion of the cord destroyed.

Now this sudden abolition of life, from a partial destruction of the spinal cord, was imputed by Le Gallois to the loss or extinction of the circulation; and this, regarded as a remote result, was in part true. But, as will have been seen, the immediate and essential effect consisted in the destruction of the organic properties of the heart and blood-vessels, by determining upon them, and all other parts embraced within the compass of experiment, a pernicious nervous influence by the sudden destruction of the spinal cord (§ 226, 227, 510) It also appeared to follow (and such was the conclusion), that the power, on which the motion of the heart depends, resides in the whole

of the spinal marrow; since the destruction of either ce. vical, dorsal, or lumbar portion, arrested the circulation. But here, again, we see the error of the conclusion; since a fatal nervous influence would be equally propagated upon the heart, not only through the continuous parts of the spinal cord and brain, but through the sympathetic nerve, by destroying any one of the three portions of the cord, and this, too, without the heart being intrinsically dependent for its motions upon

any part of the spinal marrow (§ 458, 459).

476½, f. Such, however, was the effect of the foregoing influence upon the powers of the heart; and, as the blood-vessels are, also, prostrated in their action by the same cause, it is obvious, if the extent over which the blood circulates be lessened in proportion as the heart is enfeebled, the circulation will be prolonged in parts corresponding with the portions of the spinal cord that are not destroyed. It is only necessary, therefore, to apply ligatures around the principal arteries, to answer the intention. Hence, rabbits live much longer if the aorta be tied near its emersion from the diaphragm, before destroying the respective parts of the spinal cord. By the same rule, also, if the head be cut off, before destroying the cervical portion of the spinal marrow, life is supported much longer than when the head is on.

 $476\frac{1}{2}$, g. It appears, therefore, that death resulted in Le Gallois' experiments partly from the propagation of the nervous power upon the vital properties, not only of the heart, but of all the organic viscera, and in part, also, by withdrawing the regulating medium of concerted actions, and thus deranging the organic relations (§ 129,

455, 510).

476½, h. Le Gallois found, to his surprise, and beyond his explanation, that if the spinal cord be slowly destroyed, the effects were greatly different from such as resulted from its sudden destruction; that is to say, the circulation was at once arrested when the cord was suddenly destroyed, but not so when gradually destroyed. This fact, in itself, is subversive of his principal conclusions; and the difference in results depends upon the greater violence of the nervous power when suddenly, than when more slowly excited (§ 479). This is also shown in paroxysms of joy and anger. These passions may kill on the instant, if suddenly excited, but never when gradually produced, whatever their ultimate intensity (§ 230). So a blow upon the region of the stomach, which shall not exceed in force ten pounds, may destroy life instantly, when a weight of one hundred pounds, gradually applied, may be wholly innoxious (§ 509). This is a very important law of the nervous influence, as it is in constant operation in the production and cure of diseases, whether the effects depend upon physical or mental causes. It is owing to the suddenness with which the nervous power is developed, that syncope may be occasioned by a very small loss of blood (§ 940, 961, 974), or when it proceeds from offensive sights, nauseous odors, or any mental emotion (§ 944). It is owing to the same principle, in part, that blisters often give more relief when they operate rapidly than slowly. It is an especial reason why emetics are often so suddenly curative in croup, &c.; all having their as tonishing foundation in a common principle (§ 893 i, 902 g).

477, a. I now approach the important experiments which overthrow Le Gallois', and all the conclusions which were so extensively derived from them as to organic actions, and through which, in part, I

interpret all the laws of remote sympathy, all the effects of moroific and remedial agents upon distant parts when applied to the stomach, or skin, or lungs, &c.; of the remote influences of disease, and all the effects of the passions; of blows upon the epigastrium, and the suddenly pernicious influences of surgical operations; in short, every unusual phenomenon which can be supposed to happen through the agency of the nervous power. It will be seen, also, that they corroborate, and are corroborated by, all the conclusions which I shall have drawn as to the nervous power, and its laws of reflex nervous action, from the phenomena of natural and morbid conditions, and from the discoveries in relation to the two orders of nerves (§ 464).*

Unless otherwise stated, the experiments are by Philip. A large

number are omitted, as unnecessary to my purposes.

477, b. Experiment 1. "A rabbit was deprived of sensation and voluntary motion by a blow on the occiput. Respiration ceased, but was kept up artificially. The spinal marrow was then laid bare from the occiput to the dorsal vertebræ. The chest was next opened, and the heart was found beating with considerable force. The whole cervical portion of the spinal marrow was then removed, and without affecting the action of the heart. The skull was then opened, and the whole brain removed, so that no part of the central organs remained above the vertebræ. There was, however, no abatement of the action of the heart. By suspending artificial respiration, however, about an hour and a half after the removal of the brain, the heart ceased to beat; but its action was again restored on renewing the respiration; that is, on receiving oxygenated blood.

Exp. 2. "Having rendered a rabbit insensible by a blow on the occiput, Philip destroyed the whole spinal marrow by a hot wire. Respiration was supported artificially, and, on dividing the carotid ar-

tery, the blood spouted out.

Exp. 3. "A rabbit was rendered insensible by a blow on the occiput, and artificial respiration performed. The spinal marrow, from the base of the skull to the beginning of the dorsal vertebræ, was removed, and the remaining part of it was destroyed by a hot wire. The carotid artery was then found beating, and, on dividing it, the blood rushed out with great force, per saltum.

Exp. 4. "In another rabbit, insensibility was produced in the foregoing manner, the whole spinal marrow removed, and artificial respiration not performed. The carotid artery being divided, dark-colored blood flowed per saltum. The lungs were then inflated, and florid

blood began to spout out of the artery.

Exp. 5. "In this experiment the rabbit was rendered insensible, but not motionless, by a blow on the occiput, and natural breathing continued. The spinal cord was then destroyed by a hot wire. A femoral artery was now opened, and the blood spouted out. Then the other femoral artery was opened, from which the blood flowed copicusly, and continued to flow for seven minutes; when one of the carotids was opened, from which blood issued in a full stream, and till most of the blood was evacuated.

Exp. 6. "The brain of a frog and the spinal marrow, as low as the dorsal vertebræ, were laid bare. The thorax was then opened, and the heart found acting vigorously. The part of the spinal marrow which had been laid bare was then removed, but without at all affect-

^{*} See RIGHTS OF AUTHORS p. 912.

ing either the motion of the heart, or the passage of blood through it. The brain was then removed with the same result.

Exp. 7. "The brain and spinal marrow of a frog were removed at the same time. On opening the thorax the heart was found perform-

ing the circulation freely.

Exp. 8. "A ligature was applied to the neck of a frog, the head cut off, and the spinal marrow destroyed by a wire. The circulation in the web continued afterward, for many minutes, as vigorous as in that of a healthy frog.

Exp. 9. "The spinal marrow and brain of a frog were destroyed by a wire. The animal appeared quite dead for several minutes, during which the circulation was seen in the web as vigorous as in that of a

healthy frog."

478, a. The foregoing and following experiments disprove the conclusions derived from Le Gallois', that the power, on which the motion of the heart depends, resides in the spinal cord, and in all parts of it. They also establish, what had been sufficiently shown by the heart when severed from the body, that its action may be continued without brain and spinal cord; and the proof extends equally to the blood-vessels. "From various trials," says Dr. Philip, "we found that the circulation ceases quite as soon without, as with the destruction of the spinal marrow. Loss of blood seems to be the chief cause." "The result is still more striking in cold-blooded animals, in which death takes place so slowly that the circulation continues long after the total destruction of the brain and spinal marrow" (§ 257).

478, b. The experiments prove, what will be more fully shown, that, to influence the heart and vessels through the main nervous centres an impression must be made either upon the brain or spinal cord. But the sympathetic nerve, with its central ganglia, was present, by which an exciting influence was propagated upon the great organs and bloodvessels; and however the heart and intestines may be maintained in muscular action when severed from the body (§ 264), the whole nervous mechanism, especially the ganglionic, is engaged, in natural states, in reflecting exciting influences upon those organs, the blood-vessels, &c., and thus, also, modifying the organic products (§ 113, 356 a, 399,

 $456 \ a-459 \ g$, 461, $473 \ c$, $475\frac{1}{2}$, $476 \ c$, $483 \ c$, $889 \ g$, 952).*

478, c. The experiments prove, in connection with others to be related of the same nature, that the actions of life are carried on by powers or properties inherent in each part (§ 184).

478, d. They prove that when death suddenly follows a division of the medulla oblongata, or a simple removal of the brain and spinal cord, it does so essentially by abolishing respiration, or rather as in § 510.

479. A practical consideration of great moment grows out of the difference in the modes in which the foregoing experiments were performed by Philip and Le Gallois, and the vast difference in the results. The discrepances in results were owing entirely to a difference in the size of the wires by which the two experimenters destroyed the spinal cord; Le Gallois having employed a wire that filled the cavity of the spinal column, and thus destroyed the spinal cord suddenly, while Philip used a smaller wire, and destroyed the cord gradually; or it was removed, along with the brain, without farther injury to them. In Le Gallois' experiments, therefore, the nervous influence was suddenly and powerfully transmitted through all the nerves leading from

^{*} See late Experiments with poisons, NOTE B p. 1113 .- 1862.

the spinal cord, as well as the sympathetic; while in Philip's, it was so gradual and imperfect, that it was not determined with destructive violence upon the organic properties of the heart and blood-vessels, though always with a more or less prostrating effect at first. So, too, of the sudden or gradual destruction or removal of the brain. What, also, is thus true of the heart and blood-vessels (as will farther appear), is equally so of all the other organic viscera (§ 476½ h, 509, 510, 947).

2d. On the Relation which subsists between the Heart and Vessels of Circulation, and the Nervous System; and the Influence of the Nervous System upon the Capillary Blood-vessels.

480. The following experiments are much more important than the preceding in ascertaining the existence of the nervous power, how it may be variously excited, how variously modified by artificial causes, and how it may be determined with various effects upon the organic functions. These, with another group relative to the stomach and intestines, open to us the modus operandi of the passions in organic life, of morbific and remedial agents in their effects upon parts distant from the direct seat of their operation, of sudden deaths from injuries distant from the nervous centres, of the sympathies from diseases, &c.; when taken in connection with what is known of the sensitive and motor nerves, and the reflections of the nervous power, as set forth in the laws relative to this subject (§ 462-470, 512-524).

The object in producing insensibility was to prevent all agitation of the animals, that the effects of the stimuli, &c., might be most advan-

tageously observed.

Experiments relative to the Heart in its Connection with the Nervous System.

481, a. Experiment 10. A rabbit was deprived of sensation and voluntary motion by a blow on the occiput, artificial respiration performed, and the brain and cervical part of the spinal marrow laid bare. The thorax was then opened, and the heart observed to beat with strength and regularity. Spirit of wine was then applied to the spinal marrow, and a greatly increased action of the heart was the consequence. It was afterward applied to the brain with the same effect. The increase of action was immediate and decided in both cases, and as great in one as in the other. The effect of the blow upon the head, in all the cases, was to lessen the frequency of the pulsations; as generally happens in apoplexy.

Exp. 11. The foregoing experiment was repeated, with the difference, that the whole of the spinal cord was laid bare. The motion of the heart was nearly, if not quite, as much influenced by the application of the alcohol to the dorsal, as to the cervical portion of the spinal marrow; but it was very little influenced by its application to

the lumbar portion.

481, b. We see, therefore, that experiments 10 and 11, independently of the more important ones which follow, illustrate the most essential elements that are concerned in remote sympathy, and in the operation of the passions upon organic actions, in their connection with what has been said of the sensitive and motor nerves and their relations to each other (§ 462–475). When, for instance, a morbific or remedial agent, applied to the stomach or skin, influences a remote

part, and produces, or removes, disease in that part, its primary impression is transmitted to the brain and spinal cord by the sensitive nerves, where the impression acts upon the central organs just as the alcohol did in the foregoing experiments, and, like that, it develops the nervous power which is then reflected through the incident nerves upon remote parts, just as it was to the heart in the application of the alcohol; the incident nerves in organic life being the sympathetic.

As to the passions, they are exactly equivalent to the action of agents applied directly to the brain, and develop and modify the neryous power in the same direct manner. Such as are exciting are analogous in their effects to those of alcohol; such as are depressing, to those of tobacco, opium, &c. (§ 227-230). From the equal effect of the alcohol, also, when applied directly to the spinal cord, it is evident that the nervous power is also generated in this part, as it is,

more or less, in all the nerves.

When, however, the nervous influence is developed by the primary action of alcohol on the stomach, and the action of the heart is increased in consequence, the development of the nervous influence is reflex; just as it is in respiration (§ 500). But, in all these cases, the nervous influence is developed in the brain and spinal cord by the transmitted impression, just as it is by the alcohol when applied directly to the nervous centres; the transmitted impression being exactly equivalent to the direct action of the physical agent upon the central parts (§ 1074). There is no absorption of alcohol, p. 172, no. 94.

481, c. It is now important to observe in the relative experiments upon the brain and spinal cord, that when they exist in connection, the influence of agents applied to the cord, in developing the nervous power, may be mostly exerted upon the brain (§ 459, 481 e).

Exp. 12. " Preparation the same as in Exp. 10 and 11, excepting only the anterior part of the brain was laid bare. The spirit of wine applied to this part of the brain produced as decided an effect on the motion of the heart as in Exp. 10 and 11. The spirit of wine was washed off, and a watery solution, first of opium, then of tobacco, was applied, with the effect of an increase, but of a much less increase of the heart's action, than arose from the spirit of wine. The increased action was greater from the opium than from the tobacco. The first effect of both was soon succeeded by a more languid action of the heart than that which preceded their application to the brain. This effect was greatest and came on soonest when the tobacco was used; and there was always observed, for the experiment was frequently repeated, an evident increase in the action of the heart when the tobacco was washed off. This was also seen, though in a less degree, when the opium was washed off. Little or none of this debilitating effect was observed when the spirit of wine was used. After its stimulating effect had subsided, the action of the heart returned to only about the same degree as before the application of the stimulus.

Exp. 13. "The foregoing experiment was repeated on an animal of cold blood. In this case a frog was deprived of sensibility, in less than a minute, by immersing the hind legs in the tincture of opium. Alcohol, and watery solutions of opium and tobacco, were applied to the brain and spinal cord, as in Exp. 12, and with precisely the same effects. The application and washing off of the stimulant and sedatives were frequently repeated in this experiment with the same results

It is remarkable that we could affect the motion of the heart by the agents applied to the brain and spinal marrow after they had all ceased to produce an effect on the muscles of voluntary motion through the medium of the nervous system. The action of the heart could be also influenced by these agents applied to the brain and spinal marrow long after the circulation had ceased." Of course, therefore, no action by absorption.

Exp. 14. "This experiment only differed from the last in the cer vical part of the spinal marrow and lower part of the brain being re moved, and the agents applied only to that part of the brain which lies between the eyes of the frog. Spirit of wine, opium, and tobacco, thus applied, affected the motion of the heart quite as much, and precisely in the same way, as when they were applied to the entire

brain or spinal marrow.

"The action of the heart, in the foregoing experiment, could be influenced by agents applied to the brain and spinal marrow long after

the circulation had ceased."—Note B p. 1113.

481, d. In Exp. 12, 13, and 14, we have an illustration of the modification of the nervous power according to the nature of the agents employed, while the effects correspond with such as are produced by the same agents when taken into the stomach (§ 226, &c.). It will be also observed that the effects are parallel with those of the different passions; those of the alcohol corresponding with the effects of anger and joy, and those of opium and tobacco with such as arise from grief, fear, &c. I hold that the doctrine which I have propounded as to modifications of the nervous power is established by these experiments; though abundantly shown by the phenomena arising from morbific and remedial agents. There is no other intelligible solution of the problems which they supply. In the experiments, too, it will be conceded that the nervous power was the efficient remote cause of the results; whence it follows that the nervous power must be in different states when it is excited by alcohol, opium, and tobacco, corresponding with the differences in effects (Rights of Authors, p. 912).

481, e. The foregoing Exp. 12, 13, and 14, independently of the multitude of other facts, also completely refute the doctrine of the operation of morbific and remedial agents by absorption. It will be observed that in these experiments the action of the heart could be influenced by the agents applied to the brain and spinal cord "long after the circulation had ceased." This circumstance, besides its bearing upon the doctrine of absorption, shows us how the heart is roused into action, in cases of syncope, by the application of stimulants to the

nose, cold to the surface, &c. (§ 945).

Exp. 15. "The spine of a rabbit was divided near the head, and the spinal marrow destroyed by means of a wire. Spirit of wine was then applied to the brain, which influenced the action of the heart as readily, and to as great a degree, as it does when the spinal marrow

is entire" (p. 321, § 494 e, Exp.—Note B p. 1113).
481, f. This experiment demonstrates the difficulty of forming proper conclusions as to the special functions of the brain and spinal cord, and of different parts of the brain, by any experiments (§ 459, a). It shows, however, that the action of the heart may be as powerfully influenced through the brain when the spinal marrow is destroyed, as when it is entire. The ganglionic nerve resolves the problem.

481, g. I now come to those experiments which farther illustrate the principle concerned in the sudden production of death by blows on the epigastric region, surgical operations, small loss of blood, joy, anger, &c. They also go to interpret the modus operandi of morbific and remedial agents as to their rapidity and intensity, especially when taken in connection with Exp. 10–15, and others which are to follow. The effects now supposed depend on the rapidity and intensity with which the nervous power may be excited, and reflected not only upon the heart, blood-vessels, stomach, &c., but upon the brain itself, as also upon the manner in which the nervous power may be modified by the nature of the agent, as in Exp. 12 and 13.

If the head and spinal marrow of a frog be removed, the heart continues to perform its functions perfectly for many hours, nor does it seem at all immediately affected by their removal. But, we find the effect very different when the most sudden and powerful agent is applied to them. If they are even destroyed by being sliced away, the heart, after this mode of destruction, beats on as usual. But, if either the brain or spinal cord be instantly crushed, the heart feels it

immediately and forcibly. Thus:

Exp. 16. "The thorax of a large frog being opened, the brain was crushed by the blow of a hammer. The heart immediately performed a few quick, weak contractions. It then lay quite still for about half a minute. After this, its beating returned, but it supported the circulation very imperfectly. In ten minutes after, its vigor was considerably restored; when the spinal marrow was crushed by one blow. The heart then beat quickly and feebly for a few seconds, and then seemed wholly to have lost its power. In about half a minute, it again began to beat, and in a few minutes acquired considerable power, and again supported the circulation. It beat more feebly, however, than before the spinal marrow was destroyed. It ceased to beat in about an hour and a half after the brain had been destroyed. In another frog, after the brain and spinal marrow had been wholly removed, the heart beat nine hours, gradually becoming more languid."

Exp. 17. "The foregoing experiment cannot be performed in the same way on warm-blooded animals, but it may be performed in a way equally satisfactory. In two rabbits the brain was crushed by a blow. In both the heart immediately beat with an extremely feeble and fluctuating motion. The anterior part of the brain only was crushed in another rabbit, with the same result. A strong ligature was thrown around the neck of a fourth rabbit, and at the same moment it was tightened, the head was cut off. The heart continued beating regularly, in this case, and not more quickly than in health.

All the rabbits were of the same age."

Exp. 18. The following is still more conclusive:

"The anterior part of the brain of a rabbit was crushed by a hammer. No motion of the heart was perceived by applying the hand to the side. The head was cut off, about three quarters of a minute after the brain had been crushed. No blood spouted out, and very little ran from the vessels. A strong ligature was passed round the neck of another rabbit of the same age. It was suddenly tightened, and the head cut off. In this instance the heart was found beating regularly under the finger for about three quarters of a minute. At

the end of this time, the ligature was slackened, and the blood spouted out to the distance of three feet, and continued to spout out with

great force, till nearly the whole blood was evacuated."

481, h. The last of the foregoing comparative experiments goes with others in demonstrating the error of the common opinion, that when the action of the heart and blood-vessels, or other organic functions, fail by crushing the brain, it is owing to the withdrawal of the nervous influence. But, still more conclusive is the fact that the entire brain and spinal cord may be removed without any present effect upon the actions of the heart and blood-vessels, as in Experiment 7. By this, and other considerations, I have endeavored to show that when syncope arises from loss of blood, it is not owing, as has been supposed, to the failure of the nervous influence upon the organs of circulation, but that this influence increases on the approach of syncope, is a principal cause of the paroxysm, and is actually greatest when the paroxysm is complete (§ 947, 948, and Medical and Physiological Commentaries, vol. i., p. 168–176).

482. The preceding experiments determine a variety of important points, of extensive physiological, pathological, and therapeutical application, and to which brief references were made. The whole should be viewed in connection, and also with such as are to follow; while a constant reference should be had to the laws of sympathy, as set

forth in the fifth division of our subject.

Experiments relative to the Arteries in their Connection with the Nervous System.

483, a. The next important step in our inquiry is to ascertain, in a more specific manner than the preceding experiments, how far the vessels of circulation are capable of being influenced through the brain and

spinal cord (§ 1040).

To determine the foregoing problem, it is first necessary to settle another; namely, how far the vessels of circulation can support the motion of the blood independently of the heart. That the small arteries possess this power in an eminent degree has been already rendered sufficiently certain (§ 392, 393. Also, Mcd. and Phys. Comm., vol. ii., p. 145-151, 398, 422, &c.). But we now arrive at the same knowledge by another process.—Note Q p. 1122.

As a comparative experiment, Philip passed a ligature round all the vessels attached to the heart of a frog, and then cut out the heart. "On bringing the web of one of the hind legs before the microscope, the circulation was found to be vigorous, and continued so for many

minutes; at length gradually becoming more languid."

Now, if the heart be allowed to remain, whatever impression made upon the brain shall suddenly diminish or arrest the circulation in the capillary arteries, will prove that these vessels, as well as the heart,

may be influenced by the nervous power.

Experiment 19. "The web of one of the hind legs of a frog was brought before the microscope, and while Mr. Hastings observed the circulation, which was vigorous, Dr. Philip crushed the brain with a hammer. The vessels of the web instantly lost their power, the circulation ceasing. In a short time the blood again began to move, but with less force than natural. This experiment was repeated, with the

same result. If the brain be not completely crushed, the blow increases

the rapidity of the circulation in the web."

The next experiment corresponds with those of the foregoing, which denote that the effects of the nervous power upon the organic properties and functions depend upon the manner in which it is developed, modified, and reflected. Will galvanism explain them (§ 893 a)?

Exp. 20. "The spine of a frog was laid open at the lower end, and a wire, of nearly the same dimensions with the cavity of the spine, forced through it, as in Le Gallois' experiments. The circulation was found to have wholly ceased in the web of the hind leg."

Now mark the contrast when a small wire was employed; for, in another frog the spinal cord was destroyed by introducing in the same way, and moving in various directions, a wire much smaller than the cavity of the spine. The frog soon appeared to be quite dead; but

the circulation in the web was found to be vigorous.

Exp. 21. "Part of the cranium of a frog was removed, the web of one of the hind legs brought before the microscope, and the circulation in it observed. The animal was now rendered insensible by the immersion of the other hind leg in laudanum. The insensibility did not in the least affect the circulation in the web before the microscope. Spirit of wine was then applied to the brain with an evident increase of the velocity of the blood in the web. The same effect was produced in a less degree by watery solutions of opium and tobacco. After the tobacco had been applied for about half a minute, the motion of the blood was much less rapid than before its application. On washing off the tobacco, the velocity of the blood was increased, and was again lessened on applying it. This was repeated several times with the same effects. When the circulation in the web had almost ceased after the tobacco had been washed off, its velocity was increased on applying spirit of wine to the brain."

Analogous experiments, but varied from the foregoing in some of

the details, gave the same results.

483, b. It may be proper to add, that Dr. Hall attempted to invalidate Philip's experiments with alcohol, &c., applied to the nervous centres, by repeating just one of them, and that one the least important of any. It was the least important because it was made upon a cold-blooded animal, and because, also, the state of insensibility was produced by laudanum; the experiment being no. 21, or the last of the foregoing series. Of that experiment he says that the motions of the heart were not affected on applying alcohol to the brain. It does not appear that he tried the effect of the infusions of opium and tobacco, nor that he repeated those far more important experiments upon warm-blooded animals.

The difference in the results is of the easiest explanation. By Dr. Hall's method of producing insensibility by the long-continued and extensive application of laudanum to the surface of the animal the sedative effect of the nervous influence was so powerfully determined upon the circulatory organs, that alcohol, when applied to the brain, failed of rousing the action of the heart. In Philip's experiment it is obvious that the cutaneous application of the laudanum was of short duration, and this was only relative to a few upon frogs. Dr. Hall, indeed, seems to have been aware that this objection might be raised against his experiment; for he remarks that, "I believe that there

may be one difference between Dr. Philip's experiment and my own (that is), I might apply the laudanum more effectually." It is this difference which makes all the difference in the results (§ 484 a, Ex. C. D).

Finally, the force of Dr. Philip's experiment is increased by the very objection which has been made to the production of insensibility by laudanum; since his subsequent application of a watery infusion of opium to the brain influenced the heart and blood-vessels as in those cases where insensibility had been effected by other means. And so of the following like experiments by Alston, and by Dr. Hall himself.

483, c. There is one more fact connected with the present stage of my inquiry, which it may be well to consider, and by which Dr. Hall would invalidate, still farther, the conclusion drawn by Dr. Philip from his experiment of crushing the brain. In this experiment the action of the heart is temporarily suspended. Now, Dr. Hall would argue that this suspension is not the result of any special influence exercised by the brain over the heart, during the act of violence, because the same effect will follow when the stomach is violently crushed after removal of the brain and spinal cord. Thus:

"In an eel, in which the brain had been removed, and the spinal marrow destroyed, the stomach was violently crushed with a hammer. The heart, which had previously beat vigorously sixty times in a minute, stopped suddenly and remained motionless for many seconds. It then contracted; after a long interval it contracted again, and slowly and gradually recovered an action of considerable frequency and

vigor."

Dr. Hall, therefore, argues that the nervous system had no agency in transmitting influences of the injured stomach to the heart, and that, "the organic structures (meaning others than the nervous) must have been the medium through which the effect of the violence was

conveyed to the heart."

I need not go far to indicate the capital error of Dr. Hall's conclusion, so opposed to the phenomena of the passions, and the well-known effects of cerebral hemorrhage, and blows upon the head. It is sufficient, notwithstanding the removal of the brain, and the destruction of the spinal cord, in the case of the eel, that the whole ganglionic system, all the spinal nerves, and the pneumogastric besides, remained entire. It was therefore through this vast range of most important nerves, through the great solar plexus of the sympathetic, through the whole of the anancephalous system of nerves (§ $461\frac{1}{2}$), that the nervous influence was propagated to the heart by crushing the stomach of the animal. Had, however, the brain and spinal cord been permitted to remain, the demonstrations of nervous influence upon the heart would have been more strongly pronounced. Nor was it a fair experiment to have selected a cold-blooded animal, and so tenacious of life as the eel, to contrast an important result with such as had been obtained by a very different experiment upon a warm-blooded animal.—Note B p. 1113.

But, as I have said, slight blows over the stomach of a man may destroy his life in an instant, when they would be harmless to an eel. Hunter, and others, relate instances of instant death when extirpating a testicle, or performing minor operations; and Mr. Travers, and others, from lancing a thecal abscess of the finger, and other similar

slight causes. Here, it cannot be denied, that a fatal nervous influence was thus reflected over the whole frame of a man, without calling to the explanation "the ten thousand" facts that are well established as to the influence of the nervous power upon organic actions; while we thus arrive at the obvious conclusion, that it is through the same principle blows upon the epigastrium, crushing the liver, and

similar injuries, produce their fatal effects.

But, if we concede to Dr. Hall the inconsistency in which he is involved by his experiment, and by his direct affirmation that sympathies in organic life are owing to the mutual influences of organs among each other, and without the agency of the nerves with which they are supplied, it would not affect the principle which relates to sympathy in its aspect of an important law which is constantly concerned in disease and in the operation of remedial agents. The dispute would then turn only on the nature of the cause upon which the function of sympathy depends; while the very cases of disease which Dr. Hall produces to illustrate the existence and nature of the principle are fatal to his humoral hypothesis, and go to my doctrine of reflex nervous action.

But the accuracy of all Dr. Philip's experiments has been fully as-

certained by numerous physiologists.

484, a. I shall now introduce a series of experiments by other hands which illustrate, still farther, the applicability which I have indicated

as to the preceding experiments.

In the Edinburgh Medical Essays for 1733, vol. v., p. 128, are to be found the first experiments which I shall now mention, and which appear to have been neglected by later observers. They were made by DR. ALSTON, who had no theory in view to embarrass his vision or

judgment; and yet I have met with no reference to them.

Exp. A. "I conveyed," says Alston, "through a small glass tube a few drops of a solution of opium in water into a frog's stomach, and putting the animal into a glass cylinder, adapted it so to a good microscope, that we had a distinct view of a part of the membrane between the toes of its hinder foot, where the circulation of the blood may be easily seen. My design was, since I found opium killed frogs, to observe if there was any visible change made by it in the blood itself, or in its motion. Neither of us could, indeed, see any alteration of the blood as to its consistence, color of the serum, magnitude, figure, or color, of the red globules; but we very distinctly saw a surprising diminution of the blood's velocity, for it did not move half so swiftly as it naturally does in those creatures. We alternately looked at it, again and again, and in less than half an hour saw the velocity of the blood gradually increase. The uneasy frog recovered its wonted vigor, and the blood its common velocity."

The foregoing experiment was repeated, after awhile, upon the same

frog. Alston goes on thus:

Exp. B. "I put the frog into a basin of clean water, and allowed it half an hour to refresh itself; then gave it another dose of opium. The blood then moved yet slower than it did the first time, and its velocity gradually decreasing, it at length stagnated, first in the smaller, then in the larger vessels, and in about a quarter of an hour the animal died."* The experiments were frequently repeated, with the same results.

Exp. C. The following experiment was performed by Dr. Marshall

^{*} Whyrr, in 1755, made similar experiments with the same effect.—Works, 4to, p. 310-327.—See 260.

"I applied laudanum," he says, "over the back part of a frog, carefully avoiding its contact with the web. In less than half an hour, its respiration and all sensibility had ceased, and the capillary circulation became, at the same time, more indistinctly pulsatory in the arteries, and more and more slow and feeble in the capillary vessels and veins. This effect became gradually more marked, and in two hours the circulation had ceased almost entirely in all the three sets of vessels. I now washed off the laudanum, and placed the frog in water. The circulation at first gradually, afterward more speedily, returned, and became very vivid and vigorous, even before there was the slightest return of respiration (§ 441, d). The respiration and sensibility at length also returned completely. The laudanum was reapplied and again removed with precisely the same effects. The insensibility was so perfect that the eyes were not retracted on being touched. The recovery was prompt and complete."—See § 483 b.

Exp. D. The foregoing experiment was repeated with opium and water; when the effects were less rapid, but "at length the circulation in the web ceased, and the animal became affected with complete te-

tanus."

Exp. E. "The same effect was produced more speedily on inducing the animal to swallow a few drops of the opiate solution."*

484, b. I have now to notice six principal points relative to the ex-

periments A, B, C, D, and E.

1st. In Dr. Hall's experiments (C and D), the opium was applied to the skin exclusively.

2d. The effects were exactly the same as obtained by administering

opium by the stomach (Exp. A, B, and E).

3d. The effects in both cases were similar to those obtained by Philip from applying opium to the brain, both in cold and warm-

blooded animals.

4th. The experiments by Hall and Philip fully corroborate the obvious conclusion from Alston's (Dr. Hall's being only a repetition of Alston's), that opium does not produce its effects by absorption into the circulation (as is especially supposed of this agent), since in all the experiments, and the same with tobacco in all (§ 483, Exp. 21), the effects upon the circulation went off as soon as the solutions were washed from the skin, or from the brain, and returned when they were again applied, and again promptly disappeared when the solutions were washed off. Brodie's experiment with tobacco is also in direct proof of its universal operation through the nervous centres (§ 904, b, 1088 b, c).†—Notes B I pp. 1113, 1118.

5th. It appears from the foregoing facts, that the circumstances attending the effects of opium upon the system at large are the same, whether it be applied to the nervous centres, to the stomach, or to the skin. It follows, therefore, in connection with what is known of the influences which the brain and spinal cord may exert on the actions of organic life, that the remote effects of opium, applied to the stomach or skin, are produced by a modification and reflected action of the

nervous power upon distant parts (§ 224, 226, &c.).

Here, then, we see, more and more clearly, the propriety of the application which I have made of Philip's experiments, and which will become more strikingly obvious by connecting them with the sequel,

[•] HALL, on the Influence of the Brain and Spinal Marrow upon the Circulation, p. 111

[†] Wintt applied opium to a frog after destroying the brain and spinal cord, when the heart was much less affected than when applied in the natural state.—Works, p. 513.—See § 483 c, as to sympathetic nerve, and § 1088 b, as to skin.

and with the results of Sir C. Bell's discovery. Let us suppose, for instance, that we have no other knowledge of the principle upon which remote sympathy depends, than the natural phenomena which are constantly manifested. We should certainly know, from these results, that such a principle exists; but where, or how developed, or how varied in its influences, we could not know with certainty without direct experiment. With the advantage, therefore, of such experiments as Philip's, we arrive at the clearest demonstration of the manner in which effects now under consideration are brought about, and thus put an end to the worst speculations in medicine. But, before reasoning from these experiments we should know the manner in which impressions are transmitted to the brain and spinal cord by the nerves of sensation, how they are reflected from these central organs, and the obvious results which follow in animal life, and how these results correspond with similar effects in organic life (§ 500). The foundation of an important philosophy is thus laid by demonstration, and rendered acceptable to those who rely only upon the plainest testimony of sense (§ 234).

6th. Again, I say, since the action of opium, through the stomach or skin, upon remote parts, is different from that of tobacco, alcohol, &c., and since each produces, respectively, the same effects when applied directly to the brain or spinal cord, and, in all the cases, by exciting and reflecting the nervous power, it follows that this power, like the organic powers, is capable of being modified in its nature according to the nature of the causes by which it is developed (§ 224-233,

494 с).— Nоте В р. 1113.

485. Finally, Kriemer has multiplied experiments to a great extent with reference to the part which the arteries take in the circulation, and they all concur in proving their independent action, and that they may be powerfully affected by impressions made upon the nerves. When he tied the crural nerve of quadrupeds it lessened immediately the jet of blood from the femoral artery. The same experiment on frogs arrested the capillary circulation in the web of the foot. What is also an important fact as showing an alteration of the organic properties of a part by the nervous influence, he observed that the arterial blood passed on to the veins without being converted into venous blood (§ 399, 507, 952)*—Note Q p. 1122.

- 3d. On the Principle on which the Action of the Muscles of Voluntary Motion depends, and the Relation which they bear to the Nervous System.
- 486. Philip next proved by experiments that the muscles of voluntary motion, like the heart and blood-vessels, are independent of the brain and spinal cord, as it respects their excitability and power of motion; but that they are alike capable of being stimulated through the nervous system. "We do not, surely," he says, "in the experiments which have been laid before the reader, see any difference in the nature of the muscular power of the heart, and that of the muscles of voluntary motion, except their being fitted to obey different stimuli; a difference which we find in the two sides of the heart itself" (§ 136, 188½–190). Nevertheless, the nerves supply the immediate stimulus.

^{*} This anticipates the analogous experiments which have been lately made by Cl. Bernard.—1860.

4th. Interesting Experiments were made by Philip to ascertain the comparative Effects of Stimuli applied to the Brain and Spinal Marrow on the Heart and Muscles of Voluntary Motion.

487, a. I shall state only a few of the important practical conclusions. Thus: "Another circumstance, which appears to be of great importance in tracing the cause of the different effects of stimuli applied to the brain and spinal marrow, or the muscles of voluntary and involuntary motion, is, that the heart obeys a much less powerful stimulus than the muscles of voluntary motion do. We have seen that only the most powerful chemical stimuli affect them, while all that were tried readily influenced the action of the heart and bloodvessels." This should be considered with \S 493 cc, 500 m, 687 $\frac{1}{2}$ -688.

487, b. The foregoing shows us the distinction between the irritability of the heart and voluntary muscles, &c., how it is differently affected in organic and animal life by the same agents, how the nervous power acts upon that irritability according to the nature of the agents by which it is excited, whether they be applied directly to the nervous centres or to the stomach, &c. (§ 133–162, 1883–190, 205, 206, 208,

209, 222–233, 256, 484, 500 m, 826 cc, $893\frac{1}{2}$).

487, c. It is also an important fact, as well in a therapeutical as physiological sense, and especially as distinguished from the action of the will and other things (§ 514 d), that, as the animal approached a state of death, he found that, "after all stimuli applied either to the brain or spinal cord had ceased to produce any excitement in the muscles of voluntary motion, both chemical and mechanical stimuli, so applied, still increased the action of the heart; and the irritating agents more than the mechanical" (§ 224, 500 m, nn, 637, 694 $\frac{3}{4}$, 829, 893 $\frac{1}{4}$).

487, d. It was also found by comparative experiments on the actions of animal and organic life, "that irritating or depressing agents, such as alcohol, alkalies, opium, tobacco, &c., applied to the brain, and spinal cord, exert a greater power over the heart than mechanical stimuli (such as variously injuring the structure of the brain), while the mechanical stimuli exert a greater power over the muscles of voluntary motion than the agents possessing peculiar intrinsic vir-

tues" (References above).

487, e. Again, it was found "that stimulating every part of the brain and spinal cord equally affects the action of the heart (also, the stomach and lungs), while the muscles of voluntary motion are only excited by stimuli applied to the parts of those organs from which their nerves originate; that stimuli applied to the brain and spinal cord never excite irregular action of the heart, while nothing can be more irregular than the action they excite in the muscles of voluntary motion; that their effect on those muscles is felt chiefly on their first application, but continues on the heart (and blood-vessels) as long as the stimulus is applied" (§ 233½, 506, 516, no. 6).

487, f. In connection with this comparative inquiry, Philip has a remark which is worthy of deep consideration. "It is true," he says, "that although the heart is only influenced by agents applied to a large portion of the brain, we may conceive them so applied as to produce irregular action in it; and we find that certain irritations of the nervous system have this effect. But it is evident that the heart, not being subject to stimuli whose action is confined to a small por-

tion of this organ, and being equally affected through all parts of it must render it much less subject to irregular action; which may be one of the final causes of the heart (whose regular action is of such importance in the animal economy) being made subject to the whole, and not to one part of the brain, and readily accounts for our not being able to produce irregular action in it by experiments upon the brain and spinal marrow." "When, indeed, the source of the nerves of the heart is considered, it will be found to derive its nervous influence from every part of the nervous system, and not very remarkably from any one part; a circumstance which particularly corresponds with the results of the foregoing experiments,"—and with the phenomena of sympathy as manifested in disease (§ 500 m, 1032 d).

Analogous observations are also applicable to all the other organic viscera; which farther proves that a great final cause of the ganglionic system is to unite the organs of organic life in one concerted action, while, also, it subserves their functions ($\sqrt{488\frac{1}{2}}$, $461\frac{1}{2}$ a, 1041).

487, g. By the same facts we may explain why the heart and other organic viscera are affected through the brain, and spinal cord, after their power is so far weakened as no longer to convey the influence of a stimulus to the muscles of voluntary motion. As these muscles obey stimuli applied to only a part of the brain, or spinal cord, where the nerve supplying a muscle originates, if the impression on this part be not sufficiently strong to produce a muscular movement it cannot be assisted by any other part of the brain or spinal cord. Thus, it was found by Dr. Philip, "that a blow which affects the brain generally, without materially injuring it, produces comparatively little effect on the muscles of voluntary motion, because no one part of the brain suffers greatly; but it produces a great effect on the heart, because this organ feels the sum of all the impressions. (And so of the stomach, liver, intestines, &c.) The nervous system, therefore, may be so far exhausted (or affected) as not to admit of the vivid impressions necessary to excite the muscles of voluntary motion, and yet capable of those which influence the heart," blood-vessels, &c. This is strikingly seen in apoplectic affections.—Note B p. 1113.

The philosophy of this subject is farther explained in the following luminous manner by Dr. Philip: "Here," he says, "the question arises, by what means is the one set of organs (that is, the heart, stomach, &c.) subjected to the influence of every part of the brain and spinal marrow, while others are influenced by only small parts of those nervous centres? In these latter instances, we see directly proceeding from those small parts the nerves of the parts influenced. In the former instances, we do not see, in any case, nerves going directly from all parts of these organs to the parts influenced; but we always see this part receiving nerves from a chain of ganglions, to which nerves from all parts of the brain and spinal marrow are sent. It is therefore evident, from direct experiment, that the nerves issuing from the ganglions convey to the parts, to which they send nerves the influence of all the nerves which terminate in these bodies."

By the same philosophy, so clearly founded in nature, we readily interpret the vast extent of influences which may be propagated from the stomach, or other parts in organic life, by morbific and remedial agents, through impressions transmitted to the brain and spinal cord by way of the ganglionic system; while, also, all parts of the nervous

centres may be influenced in their organic condition by impressions upon any distant part (§ 230). This application, too, of the foregoing philosophy is divested of prejudice, since it was not contemplated by

the experimenter § 1038).

487, gg. "The following case, related by the distinguished D1. Parry, on the arterial pulse, might alone be regarded as proving the existence of two sets of nerves in the extremities; the one supplying the muscles of voluntary motion, the other the powers supporting the circulation, and strikingly illustrates what has been said on this subject. 'I have seen,' says Parry, 'a total loss of pulse in one arm with coldness, but complete power of motion in that part; while the other arm was warm, and possessed a perfectly good pulse, but had lost all power of voluntary motion" (§ 113, 224, 399, 500 nn, 893½).

487, h. We may now readily perceive, from the vast difference in the results between the influence of the nervous power upon animal and organic life, how the muscular power, or strength, as it is usually called, may be excessively prostrated at the invasion of disease, while organic actions may be as greatly increased, or if depressed, they may be so modified as to require the application of remedies from which we might shrink if we regarded alone the prostration of the voluntary muscles. It is an ignorance of the principle which operates in these cases (as in the vast range of congestive fevers), and reasoning from the prostration of muscular power to a supposed analogous state of the great powers of life, and thus mistaking mere prostration of animal life for absolute "debility" of the organic viscera, that has led so extensively to the administration of stimulants and tonics, where bloodletting and analogous agents are most imperatively required. The mind, too, is inoperative in all these conditions, and the voluntary muscles languid, in consequence; and the very failure of the will to rouse them into action, where drowsiness has contributed its effect, has been often regarded as an evidence of that "debility" which calls for the "stimulant plan of treatment" (§ 473, 961, $893\frac{1}{2}$).

It cannot, therefore, be too strongly enforced, that in all cases of sudden prostration at the invasion of fever the nervous power has a principal agency in the phenomenon,—that its influences on animal and organic life are widely different,—that it simply fails to stimulate the voluntary muscles, and hence the greater amount of apparent "debility;" while in relation to the organic processes, it has been so modified as not only to exalt, or perhaps depress, the forces of life, but to alter profoundly their very nature (§ 476 c, 500 h, nn, 893½).

There is nothing in the whole range of medical philosophy so practically important as these considerations (§ 569, 961, 967). It is a subject, however, which requires thought for its proper understanding, as well as a comprehensive view of profound laws in physiology. It is therefore repulsive to the many, who will rather rest upon the simple chemical and physical hypotheses than contemplate Nature in her dignified and rational aspects. The charm of simplicity which hung around the celebrated theory of John Brown encircles, also, the humoral and other chemical hypotheses, and adds its fatal delusion to those prevailing doctrines (1068 a).—Notes Ee p. 1133, Ff p. 1135.

488. An important remark is made by Philip at the close of his experiments relative to the functions of the heart, blood-vessels, and coluntary muscles, and their essential independence of the nervous

system, which goes to corroborate the conclusions I have drawn as to the agency of the nervous power in the healthy and morbid processes, of its modifications according to the nature of the agents by which it is developed, &c.; and this the more so, as Dr. Philip had formed no such inferences, but regarded the nervous power as the galvanic fluid, stimulating the various parts of the system, and a mere chemical agent in the formation of the secretions. I refer particularly to the clause in italics.

"It not only appears," says Dr. Philip, "from the experiments which I have laid before the reader, that the power of the heart and vessels of circulation is independent of the nervous system, but that that of the muscles of voluntary motion is so likewise, and that these, like the former, are only subjected to this system IN THE SAME WAY in which they are subjected to every other agent that is capable of exciting them. Thus we find, that all the moving powers of the animal body, as far as we have hitherto traced them, are independent of the nervous system, but that this system is equally capable of acting as a stimulus to them, although in different ways, whether they are subject to the influence of the will or not" (§ 133–162, 188½–190, 222–233, 205, 206, 208, 209, 256, 476 c, 484, 500 h, m, 826 cc, 893½).

488. I shall now advert, once more, to the remarkable distinction between the operations of the nervous power as manifested in animal and organic life (§ 96-110). In animal life, the nervous power constantly influences, in a sensible manner, all the involuntary actions, and is obedient to the will in respect to all the voluntary muscles (§ 245, 476 c, 500 h). Its intensity of action, and consequent manifestations, depend upon the force or intensity of the exciting causes. For these habitual functions of the nervous power the cerebro-spinal system is specifically provided. Coming to the organs of organic life, we find them supplied with a system of nerves remarkably different from the cerebro-spinal, and a corresponding difference in the laws of nervous influence. This system serves as a medium through which the cerebro-spinal operates in organic life, possesses in its ganglia centres of reflex action which combine tributary influences from different parts of the cerebro-spinal, unites the organic viscera, supplies the stimulus to organic muscular tissue, and contributes a vitalizing effect upon organic compounds through a modifying influence upon the organic functions (§ 224, 226, 409 k, 456 a, $461\frac{1}{2}$ a, 473 c, $475\frac{1}{2}$, 500 m, 893 a, c.)

But there is this coincidence in the actions of the two lives; namely, the power which generates motion, both in animal and organic life, is independent of the nervous system (§ 205–215); but the nervous power is equally capable of influencing its operation, though in different modes (§ 226–233, 454–461½, 500, 893½).

489. The question is investigated by Philip, "whether the power of secretion is also independent of, though influenced by, the nervous system."

Though settled by experiment, the analogies supplied by the vegetable kingdom are amply conclusive that the nervous system is only an excitant to the function of secretion, and dispenses a modifying influence upon organic compounds (§ 224, 409 k, 456 a, 461½ a, 488½, 893½).

From Philip's, and the experiments of others, it results, for example, that a division of the pneumogastric nerves either destroys or greatly impairs the digestion of food. But, says Philip, "it deserves notice, that the food, in such cases, is found covered with apparently

the same semi-fluid which we find covering the food in a healthy stomach;" and "the lungs are found distended with a frothy fluid, which fills the bronchi and air-cells" (§ 461).

It follows, therefore, that the function of secretion, and its *products*, are so far independent of the nervous system as to be only influenced through that system. Such is the inevitable conclusion from the experiments themselves; and yet their author was led into an important error by his hypothesis of the identity of the nervous power and galvanism (\$ 409 hh, k, 493 cc, 893 $\frac{1}{2}$, 902, 905 a, 1040).

5th. On the Principle on which the Action of the Alimentary Canal depends.

490. Philip destroyed separately, and simultaneously, the brain and spinal cord, and, in other instances removed both at the same time. In all the cases "the motion of the stomach and intestines continued till the parts became cold, so that when the intestines exposed to the air have lost their power, that of those beneath still remains." "It appears from these experiments that the power of the stomach and intestines, like that of the heart and blood-vessels, resides in themselves, and is wholly independent of any influence derived from the nervous system." This is true as to the moving power; but the experiment is defective in neglecting the sympathetic nerve, by whose reflex action the peristaltic movements were maintained (§ 889 g). In § $476\frac{1}{2}c$ the air and mechanical irritation were equivalent to the stimulus of the nervous power § 473c, 478b, 483c, 462-464, 498e).

6th. On the Relation which the Alimentary Canal and Lungs bear to the Nervous System.

491. Direct experiments, as in the foregoing cases, by agents applied to the brain and spinal cord, show that the stomach, intestines, and lungs may be influenced through the nervous centres. "It often appeared," says Philip, "that spirit of wine applied to the brain and spinal marrow increased the motion of the canal;" that "the stomach, like the heart, is capable of being influenced by every part of the brain and spinal marrow" (§ 487 g). For these important investigations the reader is referred to the work itself.

Review of the Inferences from the preceding Experiments.

492. The following inferences are made by Dr. Philip in relation to his various experiments, and it will be seen that they are generally correct, and may be applied to the most important problems in physiology and practical medicine:

1. "That the vessels of circulation possess a power capable of supporting a certain motion of the blood independently of the heart.

2. "That the power both of the heart and vessels of circulation is independent of the brain and spinal marrow.

3. That the nervous influence is capable of acting as a stimulus both to the heart and vessels of circulation.

4. "That the nervous influence is capable of acting as a sedative both to the heart and vessels of circulation, even to such a degree as to destroy their power.

5. "That the effect of the sedative is not the result of an excess of stimulus, but, like excitement, the direct operation of the agent.

6. "That the power of the muscles of voluntary motion is independ-

ent of the nervous system, and that their relation to this system is of the same nature with that of the heart and vessels of circulation, the nervous power influencing them in no other way than as other stimuli

and sedatives do.

7. "That the cause of the muscles of voluntary and involuntary motion appearing, at first view, to differ essentially in their nature, is their being excited by stimuli essentially different; the former being always excited by the nervous influence, the latter, though occasionally excited by this influence, in all their usual functions obeying other stimuli. [This must be qualified as in § 456 a, $461\frac{1}{2}$ a, $488\frac{1}{2}$, $893\frac{1}{2}$.]

8. "That the brain and spinal marrow act, each of them, directly

on the heart, as well as on the muscles of voluntary motion.

9. "That the laws which regulate the effects of stimuli applied to the brain and spinal marrow, or the heart and muscles of voluntary motion, are different.

[This affirmation can be made only of certain differences in the modes in which vital agents affect the heart and voluntary muscles. A common principle is at the foundation of the whole (§ 500, h, 893½).]

10. "That mechanical stimuli applied to the brain and spinal marrow are better fitted to excite the muscles of voluntary motion, and chemical stimuli the heart.

11. "That the heart obeys a much less powerful stimulus applied to the brain and spinal marrow than the muscles of voluntary motion do.

12. "That stimuli applied to the brain and spinal marrow excite

irregular action in the muscles of voluntary motion.

13. "That no stimulus applied to the brain and spinal marrow excites irregular action in the heart or vessels of circulation, nor is their action rendered irregular by sedatives, unless a blow, which crushes a considerable part of the brain or spinal marrow, be regarded as a sed-

14. "That the excitement of the muscles of voluntary motion takes place chiefly at the moment at which the stimulus is applied to the brain and spinal marrow, while that of the heart may generally be perceived as long as the stimulus is applied.

15. "That after all stimuli applied to the brain and spinal marrow fail to excite the muscles of voluntary motion, both mechanical and

chemical stimuli, so applied, still excite the heart.

16. "That the vessels of secretion, like the vessels of circulation,

are independent of, but influenced by, the nervous system.

17. "That the peristaltic motion of the stomach and intestines is independent of the nervous system, [excepting its stimulus & 478 b].

18. "That their motion is capable of being influenced through the

nervous system.

19. "That the stomach and lungs, like the sanguiferous system, are

influenced by every part of the brain and spinal marrow.

20. "That the proof of the vessels possessing a principle of motion in dependent of their elasticity, which bears the same relation to the neryous system as the excitability of the heart, not only as far as respects the kind of influence which they derive from that system, and the way in which it is supplied to them, but also as far as respects the purposes for which it seems to be bestowed on them, affords a strong argument for believing that this power is of the same nature with that of the heart."

493, a. It is remarkable that the sagacious mind of Dr. Philip should have fallen into the error of deducing from his experiments the identity of galvanism and the nervous power, and the dependence of the secreted substances upon that principle. "The vessels of secretion," he says, "only convey the fluids to be operated upon by the nervous influence." Here the "influence" is regarded strictly as a chemical agent. But, at the same time, he unavoidably concludes that "the vessels of secretion, like the vessels of circulation, are independent of, but influenced by, the nervous system;" galvanism, however, being the supposed agent in all the cases.* And yet Dr. Philip, through the light of galvanism, is led to the contradictory statement, "that, although the powers of circulation are independent of the nervous system, those of secretion are very far from being so." And, as to the products themselves, had he, or had others subsequently, considered the simplicity of the laws of Nature, and the remarkable Unity of Design which prevails in the fundamental constitution of all organic beings, from the humblest plant up to man, it never could have been entertained that the powers which circulate the blood, like those of the sap in the vegetable kingdom, and govern the action of the secreting vessels, are not derived from the nervous system, and yet that the formation of the secreted products is the work of the nerves. There is nowhere in Nature so great a violation of consistency; while, also, secretion is just as much a function of vegetables as of animals (§ 638). I am not, however, unmindful of the indisposition to predicate of final causes, or of any obvious Design, the intentions to be fulfilled, or any principle in philosophy which may be involved in the Plans of the Creator (§ $350\frac{3}{4}$, kk). But, since every thing in nature emanates from its fundamental constitution, I can have little doubt that we shall be gradually led to recognize the connection of philosophy with the Works of its Author, and to acknowledge that in all philosophy we are employed in seeking out the Institutions which He spoke into existence. and in doing which we may derive much assistance from going beyoud the immediate phenomena, and thus, also, render philosophy and natural Religion, and of course, therefore, Revelation, subservient to each other.

493, b. Dr. Philip also adopted the error, which had been long propagated, of regarding the brain as a mere galvanic battery, and of course designed for the generation of galvanic fluid, and thus gave a farther impulse to those chemical hypotheses of life which have so extensively usurped the place of medical philosophy, was compelled to embrace these hypotheses himself, and thus to advance the very errors which have contributed to obscure the light which his experiments reflect upon every department of medicine (§ 350, nos. 5, 18-20, 42). It was his misfortune to have come upon the stage just at the overthrow of that philosophy which had been so highly advanced by Hunter, Bichat, Cullen, and their compeers, and the revival of the exploded physical and chemical doctrines of life, and of the humoral pathology. But his experiments must endure forever.

493, c. Again, having assumed that "the brain and spinal marrow are necessary to the function of secretion," Philip raises an objection which he foresaw would prevail. This objection consists in the ma-

^{*} See Medical and Physiological Commentaries, vol. i., p. 52-68, 107-119, where the subject of galvanism is fully examined.

turity of the fœtus without brain and spinal cord; and to defend the chemical hypothesis, and the assumed identity of the nervous power and galvanism, and neglecting the sympathetic nerve, he assumes, that, when the brain and spinal marrow are absent, the uterus performs the functions of those parts to the fœtus; that is, it acts exactly as the brain and spinal cord in supplying the nervous power.* But this conjecture, independently of the absence of every fact, is contradicted by the total want of the requisite analogy between these two systems of organs. To give greater plausibility to the hypothesis, Philip remarks, that "no writer has before attempted to explain the difficulty."

493, cc. I shall have introduced many facts to disprove the depend-The agency ence of animal products upon galvanism or catalysis. of the former, as we have seen, is positively contradicted by the fact that plants, which are destitute of nerves, generate compounds very similar to animal (§ 409 hh); and farther on is an argument drawn from the electrical circle (§ 893 a). Again, cerebro-spinal nerves simply excite the voluntary muscles, while the sympathetic not only excites the organic muscular tissue, but exerts a peculiar vitalizing influence upon the organic products (§ 893½). Now, I submit that no reason can be assigned why galvanism should, according to Chemistry, act as a decompounding agent upon the blood when exercised through the sympathetic nerve, but not through cerebro-spinal nerves-especially as Chemistry alleges that it is an oxydizing agent of all muscular fibre. It need scarcely be added that whatever nervous influence is exerted upon the blood, it is, in all parts, through the sympathetic nerve (\$ 111-117, 224, 226, 356 a, 409 hh, k, 456 a, 461, $475\frac{1}{2}$, $489\frac{1}{2}$, $893\frac{1}{2}$).

493, d. Moreover, the eminent man who has contributed so largely to the philosophy of life falls into another common error now taught by the schools. Thus: "It is not to be overlooked," he says, "that the vessels convey the fluids to be operated upon by the extreme parts of the nervous system in a peculiar way. By the diminished capacities of the capillary vessels the blood is divided as by a fine strainer, some of its parts being too gross to enter the smaller vessels." "This," he adds, "is necessary to prepare the blood for the due action of the nervous

influence" (§ 183, &c., 399, 408-411, 748).

Now, what can be more inadmissible than the comparison of the living, organized vessels, whose *actions* are *proved* by Dr. Philip to be influenced by the nervous power, to a set of dead, inorganic tubes?

In consequence of the foregoing mechanical hypothesis, Dr. Philip is compelled to give in his adhesion to the present physical doctrines of inflammation, as set forth in the sequel (§ 748, &c.). This, too, may be regarded as a principal reason why his experiments have not been applied to the philosophy of disease and therapeutics (§ 476 a).

Philip thus lost the opportunity of applying his observations to any useful or practical purpose. Nevertheless, his very misapprehension of their true import, and his diversion from the path of Nature, impart to them that inestimable value which belongs to the conviction that the facts lead only to the truth where they were intended for the support of error (§ 5\frac{1}{4}, 188\frac{1}{2}d).—See Rights of Authors, p. 912.

494, a. In concluding this important subject, I shall bring up the late experiments by Van Deen, Stilling, Budge, and others, by which those of Philip have been again confirmed, and the results extended.

^{*} This may be placed in the same category as some other "vicarious functions" of distinguished physiologists, as in \S 83 b, 1086.

It will be seen that they have a very specific bearing upon the doctrines of humoralism (§ 819, &c.), and upon the modus operandi of morbific and remedial agents (§ 893, &c.). It might have been useful to have stated them in immediate connection with either of those subjects; but they should form a part of the combined force which marches in

advance upon the regular plan of organization.

494, b. Exp.—After Fontana had made more than 6000 experiments, in which he employed more than 3000 vipers, and caused to be bitten more than 4000 animals, to extort the conclusion that the poison of the viper kills all animals by acting upon the blood, the whole of those 6000 experiments were overturned by a single one by Girtanner; showing that the poison will kill frogs entirely deprived of blood in as short a time as it kills those which have not lost their blood.

The conclusive nature of Girtanner's experiment has been entirely disregarded by subsequent humoralists, whether as it respects the operation of morbific, or of remedial agents; or more probably the experi-

ment is unknown to most, or forgotten.

The late experiments by Van Deen and Stilling are of the same import as Girtanner's, and again call upon physiologists to return upon the path of nature. Of these experiments I shall present one or two only, as being sufficient for every intelligible purpose connected with my subject.—Note B p. 1113.

It should be premised, that when all the viscera, the heart, bloodvessels, &c., are removed from frogs, so that nothing remains but bones, muscle, and nerves (as was done in Girtanner's experiment), the animal will hop about for half an hour, and appear in all respects as nat-

ural as in its perfect state. (See, also, Spallanzani, § 441, f.) 494, c. Exp.—The frogs being thus completely eviscerated, and all vascular connections with the spinal cord destroyed, Van Deen divided the cord through the third vertebra, and then introduced within the mouth a drop or two of the acetate of strychnia. In a few minutes, the parts above the section of the cord were affected with spasm. while those below were unaffected.

494, d. Exp.—Again, Stilling also eviscerated many frogs, after the foregoing manner, and, on applying acetic acid to the skin, as late as half an hour after the evisceration, he excited reflex movements.

494, dd. Observe, too, how an important modification of these experiments goes to the same conclusion. Stilling exposed the spinal cord of a frog thus completely eviscerated, and touched it with a solution of the acetate of strychnia, which gave rise to the same general tetanus as when strychnia was applied to the mouth or skin. Even an isolated portion of the cord would give rise to spasm in parts supplied by that portion, on being touched with the solution. From this fact, Stilling draws the conclusion, that if the cord be divided in numerous places, each portion is a nervous system in itself, and capable of transmitting influences through communicating motor nerves, independently of the brain, or of other parts of the cord (§ 459, 828).

In the foregoing experiments, which are only examples of a great variety by the same physiologists, we have another full confirmation of the preceding ones by Philip with the additional advantage of other agents to obtain the corresponding results. Nor will the reader fail to observe that the same remarkable phenomena occurred in the eviscerated frogs when acetic acid was applied to the skin as when the

acetate of strychnia was applied within the mouth, as in Van Deen's experiment (§ 494, c). This is an important element in interpreting the sympathetic influences of remedial and morbific agents when applied to the surface of the body (§ $1088 \ b$).

It will be also seen that the foregoing experiments upon the skin

coincide with those by Alston, made in 1733 (§ 484).*

These observations put at rest Müller's interpretation of the action of prussic acid in producing instantaneous death when a drop is applied to the tongue, and which has been extensively employed by the humoralists to preserve the purity of their doctrines. The more we consider the profound familiarity of the Berlin Philosopher with the laws of the physiological state of the nervous system, and his full recognition of the vital principle and all its attributes, the more are we surprised at his universal doctrine of physical absorption, and his extreme defense of the humoral pathology, as evinced in the following extract from his *Elements of Physiology*. Thus:

"The rapid effects of prussic acid can only be explained by its possessing great volatility and power of expansion, by which it is enabled to diffuse itself through the blood more rapidly than that fluid circulates, to permeate the animal tissues very quickly, and in a manner independent of its distribution by means of the blood," &c. And yet, in the same paragraph he states that nux vomica, which is not volatile, will produce the same speedy death (§ 500 c, 826 c, 827 d. Also, Med. and Phys. Comm., vol. i., p. 565, 569, text and notes).

And again, says Müller, "My experiments, as well as many others, instituted by well-known physiologists, prove that, before narcotic poisons can exert their general effects on the nervous system, they must enter the circulation" (§ 657, 827 d-829, 904 b, 1032 d, 1066).

Müller's doctrine, I may also say, that the absorbent vessels have no visible orifices, and his physiological construction of their function, leads him to the propagation of errors which have vitiated the whole fabric of physiology and medicine. The doctrine may be summarily expressed in the following language of its author. Thus:

"The primary phenomenon of the immediate absorption of substances in solution into the blood is the permeation of animal tissues by the fluids. The property of permeation by fluids possessed by tissues, even after death, depends upon their invisible porosity, and is termed imbibition." Some of the consequences may be seen in sec-

tions 289, 291, 350, no. 24, 350\frac{1}{2} n, 514\frac{1}{2} b.—See \\$ 1089.

494, e. What I have now stated of the experiments by Van Deen and Stilling relates particularly to influences exerted in animal life, though, like Philip, they have corresponding experiments in organic life. These it would be superfluous to repeat, especially as some of the foregoing involve a complex agency of the ganglionic nerve (§ 516, no. 13).

Budge, however, has lately made a multitude of experiments with a view to the physiological relations of the cerebro-spinal and sympathetic systems. There is novelty about them, and they go far in sustaining my philosophy of remote sympathy, and in all its wonderful details, and in corroborating that philosophy which I originally set forth in the "Commentaries" as to the modus operandi of morbific and remedial agents (Rights of Authors, p. 915).

It will be observed, also, of Budge's experiments, that they are anal-

^{*} Whytt's experiment of killing frogs deprived of heart by giving them opium (1755) is also perfectly conclusive against absorption by the intestine.—Works, 4to, p. 200-302, 310, 320.

ogous to those which have been made by introducing different agents into the stomach capable of affecting the great nervous centres, and thus deducing the special influences of certain functions of the brain upon distant parts. The experiments in which the nervous centres were irritated should be, particularly, compared with those by Philip,

in which he employed alcohol and tobacco. Thus:

Exp.—The heart of a frog having ceased to beat but once in fourteen seconds, the anterior cords of the cervical portion of the spinal marrow and of the medulla oblongata were irritated, when the heart beat once in three seconds. On first irritating the posterior cords, no effect ensued. In other experiments the action of the heart was restored, after it had ceased to beat, by irritating the anterior cords of the medulla oblongata with a needle, or by caustic potash. So, also, airritation of the corpus callosum reproduced the actions of the heart. Irritation of the cerebellum restored the movements of the stomach, and brought on vigorous contractions of the colon and urinary bladder. The last two organs were also affected in the same way by irritating the anterior part of the spinal cord (p. 303, § 481 e, Exp. 15).

The young student should be careful not to confound these move ments with those of continuous sympathy, as exhibited in § 498, &c. The foregoing are effected by a determination of the nervous power

upon the organic properties of the several parts (§ 222, &c.).

IV. OF THE VARIETIES OR KINDS OF SYMPATHY.

495. We have hitherto seen that the several properties of life are distinguished by remarkable modifications, and that in some of the instances the varieties are so great as to amount to distinctions in kind (§ 133-163, 175, 177, 185, 190, 191, 197, 200, 215, 217, 219, 220, 226-230). And so, also, more or less, of the functions. The same rule obtains as to sympathy, this function having been divided by Mr. Hunter into remote, contiguous, and continuous (§ 452, &c.).

496. Remote sympathy is the principal condition of the function. Its office is the transmission of impressions, whether natural, morbific, or remedial, to and from parts separate from each other, or different parts of a compound organ, or through which the nervous influence is determined on parts which receive the primary impressions, or when that influence proceeds from direct impressions, physical or mental, upon the cerebro-spinal system itself (§ 230). In the last case, the rationale of the function is very analogous to that of voluntary motion (§ 233). In the former, it is reflex action of the nervous system.

497. Contiguous sympathy is a circumscribed condition of remote sympathy. Its peculiarity is shown by the effects of blisters, leeches, and various other external applications, in relieving internal disease, in proportion as they are applied most immediately over the internal part. Doubtless the centre of this kind of sympathy, or where the nervous power is excited and reflected, is the ganglia of the ganglionic system, or perhaps some plexus of nerves, or some parts of the sympathetic nerve itself (§ 473, no. 2, c; § 516 d, 893 a, 905). It should be observed, however, in these cases, that remote sympathy, in its clear acceptation, is brought into action (§ 1038).

The apparent effects of contiguous sympathy, however, may be sometimes explained, especially in consecutive morbid processes, by

the irritation from enlarged vessels, or from effusions of coagulable lymph, or dryness of surface, &c., as in pleurisy and ophthalmia.

498, a. Continuous sympathy is independent of the nerves, except as they enter into compound tissues. It is most strongly pronounced when unusual stimuli operate, and it always occurs in the tissue, or another continuous with it, upon which the primary impression is made. I would prefer calling it continuous influence (§ 1042).

498, b. Its mode of propagation consists in the condition of a particular part of a tissue, where some impression is made upon the organic properties, being extended to other parts continuous with it, in uninterrupted succession; though the changes may be much more intense in some parts of the tissue than in others (§ 516, no. 2).

498, c. In the natural condition of the being the operation of this principle is strikingly manifested in the various sensible motions of

plants. For example,

"To excite the motion of the leaflets and petiole of the mimosa, it is not necessary that either the intumescence itself, or even the leaves, should be touched. The stimulus may be applied to a more or less distant part. Even the roots transmit the excitation to the leaves. M. Dutrochet moistened a small portion of the roots of the mimosa with sulphuric acid, and, before there was time for the absorption of the acid to have taken place, the leaves became folded" (§ 289).—Muller's Physiology.

And yet we learn from able physiologists that the whole connected movements of plants, in their circulation, and other organic actions, depend upon purely physical causes (§ 257, 261, 289-291, 293,

294, 303, 304, 1053–1055).

498, d. In the animal body, I have shown that the contractions and dilatations of the veins are greatly owing to continuous sympathy, the immediate exciting causes consisting in the existing state of the communicating arteries and the variable quantities of transmitted blood. Here, too, as in the circulation of the sap, the propagation of the continuous sympathy or continuous influence is exceedingly rapid, and results in a corresponding development of motion (§ 794, 795).

498, c. Again, as exemplifying the existence of continuous sympathy, and its independence of proper nervous action, take another fact from the animal kingdom, showing the action of other stimuli;

In the heart of many animals, "cut out and left undisturbed until the frequency of its beats shall have so far diminished that considerable intervals intervene between the contractions (or if it have entirely ceased to beat), mechanical irritation by means of a needle excites a contraction which cannot be confounded with the regular beats; and, at whatever part the irritation be applied, the reaction is the same as if the whole heart had been irritated; that is to say, there ensues a contraction not at one point only, but of the whole organ."—MULLER'S Physiol. A central ganglion would be necessary to nervous action.*

Bichat says of the foregoing experiment, if the action of the heart be allowed to cease entirely, and the organ be then pricked, it will not only begin to act again, but that a dilatation of the cavities will sometimes take place first. The action, too, may not begin till some seconds after the part is irritated (§ 264, 265, 475½, 516 d, 637, 647½).

498, f. Continuous sympathy is an important element in the physiology of disease and of therapeutics. This is conspicuously seen in

^{*} See Notes A p, 1111, BB p, 1131.

the propagation of inflammation from a central point. In a therapeutical sense, it is seen in the relief of hepatic congestions by leeches applied to the anus; when, besides the direct effect from loss of blood, the peculiar vital impression which is made upon the organic properties of the mucous tissue of the rectum by this mode of abstracting blood is propagated progressively along the whole tract of the membrane up to the duct of the liver, along which it is extended to the organ itself, whose secretion is thus, in part, increased, and the organ otherwise brought under a salutary influence. But, it is also true, that the impression which is made upon the intestinal mucous membrane is propagated to the brain and spinal cord by way of the sympathetic nerve, from whence the nervous power is reflected upon the liver, skin, &c., with a salutary effect, through the motor fibres of the same nerve; and thus remote sympathy is simultaneously brought into operation (§ 523, no. 6. Also, Medical and Physiological Commentaries, vol. i., p. 135, &c.).—Rights of Authors, p. 912.

498, g. The continuous impression, in the foregoing case, upon the intestinal mucous membrane, is equivalent, in principle, to that which is produced by cathartics; so that reflex nervous influences may be propagated from all parts of the canal, as well as from the verge of the anus. Exactly the same order of influences springs from enemas and suppositories, whether of a sedative or purgative nature (§ 526). In all the cases, the functions of the liver are reached through the instrumentality of the intestinal mucous tissue, just as mechanical irritations of the conjunctiva, or of the membrane of the mouth, affect the lachrymal, or the salivary glands (§ 923, 524 a).*

498, h. Whether continuous sympathy will give rise to reflex nervous actions, and to what extent, will depend greatly upon the nature of the causes and the tissue affected (§ 135-152). It is strongly manifested in all irritations of the alimentary mucous tissue, but is seen but little or not at all in irritations of the muscular tissue, animal or organic.

499. The brain and spinal cord are, therefore, the sources of general reflex nervous action; but the ganglionic system not only participates in all the reflected actions upon the organic viscera when proceeding from the cerebro-spinal, but supplies in its ganglia, plexuses, &c., local centres of reflex action known as contiguous sympathy (§ 455, 456 a, 458, 459, 473 c, 478 b, 483 c, 490, 893 a, 905 a).

500, a. Remote sympathy may depend either upon impressions made upon the sensibility of parts distant from the nervous centres, or directly upon the centres themselves. In one case the function is associated with sympathetic sensation, in the other it is not (§ 451).

500, b. When made upon distant parts, the impression is transmitted to the nervous centres through nerves of sensation or the sensitive fibres of compound nerves, and brings the nervous power in those centres into unusual operation, from which this power is reflected through nerves of motion, or the motor fibres of compound nerves, upon the irritability of other parts, or of the part which sustained the primary impression, and thus gives rise to those various results which are the prominent phenomena of reflex nervous action (§ 455 d, 464-471), and which for brevity, I call remote sympathy, or sympathy.

500, c. The ordinary results of remote sympathy will follow impressions made directly upon the nervous centres, and, indeed, upon the trunks of nerves (§ 474, 507). These impressions may be made

* See Note U p. 1126.

upon the brain and spinal cord, and by all kinds of physical agents. and by the mind and its passions. The physical and the mental are alike operative. They rouse the nervous power, and modify it according to the nature of the cause, as in the former case (b); when it is transmitted to other parts, as in the more complex process (§ 222-233, 476-492). If the brain or spinal cord be irritated by the direct application of alcohol, it will increase the action of the heart and blood-vessels; or, on the contrary, their action will be diminished by the application of tobacco, opium, &c. (§ 476, &c.). And just so with the different passions, and emotions. Joy produces a lively action of the heart and all the cutaneous vessels; anger a more violent state of general arterial excitement; shame suffuses the face in one way, and love in another; fear subdues the action of the heart and capillaries, induces palpitation, covers the body with a cold sweat, and leads to unwonted micturition; jealousy is attended by other remarkable results in organic life; grief undermines digestion, &c. Disgusting sights, like emetics, produce vomiting, as will even their recollection. These cases are all coincident with those in which organic actions are influenced by irritating the brain or spinal cord mechanically, and involve exactly the same essential principle which is concerned in the most complex processes of reflex nervous action (§ 476, &c., 508). I call it direct action (§ 227).

500, d. The operation of the will, in producing voluntary motion, follows the same rule as that of the passions. Each is equally a cause of development of the nervous power. The will merely acts as a stimulus to the brain, by which the nervous power is developed and transmitted to the voluntary muscles, where, by its operation upon mobility, through irritability, voluntary motion is produced (§ 215, 226, 233,

243-246, 258, 467, 476 c, $818\frac{1}{2}$, 1072 b).

"Irritability," says the able Macbride, "is to be held as a requisite foundation for the power of voluntary motion; for, if we may be allowed to make a comparison, the soul would be no more capable of moving any particular muscle, or set of muscles, if their fibres, in general, had not the property of irritability, than a musician would be capable of bringing music out of a violin, if its strings were not endowed with the property of elasticity" (§ 189, 206).

And this shows, us, also, the final cause of the exquisite endowment of all muscles in organic and animal life with irritability, while they

possess only a low degree of sensibility (§ 193, 206).

We thus see, too, another remarkable exemplification of the manner in which the nervous power is so excited by the nature of the exciting cause that it shall give rise to voluntary motion. That the will acts as a stimulus, only, to the brain, and that voluntary motion is excited by the stimulus of the nervous power is manifest from the coincidence between voluntary motion and the spasmodic affections of the same muscles that arise from irritations of the gums or of the intestinal canal. The same is shown by the spasmodic actions induced by nux vomica, in paralytic affections; which also illustrates the distinction between irritability and sensibility, and shows that motion is effected by the organic properties (§ 184 a, 188, 193, 195, 206, 208). In this case, sensibility may be very obtuse in the affected limb, while the agent will exert a greater spasmodic effect on the paralyzed than on the sound muscles. This greater effect is owing to the morbid

development of irritability. And what farther illustrates the philosophy as to the action of the nervous power upon irritability in rousing paralyzed muscles, is the opposite effect of conia; for, in this case, conia paralyzes the muscles without impairing sensibility (§ 487, gg).

In all these cases of spasmodic action the irritations are propagated upon the cerebro-spinal axis, and prove an exciting cause of the nervous power; in the case of the will the irritation is direct in its analogous function of voluntary motion. But the coincidence is more perfect between the voluntary movements and the involuntary ones that are consequent upon irritations of the brain or spinal cord, as in Philip's Experiments, where the physical irritations are direct, and, therefore, upon common ground with the will and the passions (§ 477, &c.).

500, dd. The action of the will generally terminates in the muscles moved, but gives rise to reflex actions in roosting, &c., by placing the muscles in a rigid position, which acts as an exciting cause.* Mental emotions are but rarely reverberated in cases like transient blushing, but commonly give rise to reflex actions when they operate profoundly, as in vomiting, fear, grief, &c. (§ 500 i, k, 514 f-m, Index II., ROOSTING).

500, e. Motion is produced in muscles that are partly voluntary and partly involuntary (as those of respiration) through the principles now stated; and the modus operandi of their involuntary movements also illustrates fully the philosophy of voluntary motion. Thus, in the involuntary act of respiration some peculiar impression upon the lungs, arising, perhaps, from want of air, is the cause of that development and transmission of the nervous power to the respiratory muscles which induces an action precisely similar to that which is excited in the same muscles by an act of the will. The only apparent difference is, that in the latter case the nervous power is excited by the will, and not, as in the other case, by an impression transmitted to the brain from the pulmonary mucous membrane. It appears to be a common phenomenon, also, for the will to determine the nervous power upon the muscular coat of the intestine, just as it is by the reflex nervous action of a cathartic. This is evinced by the quickened peristaltic action when on the way to the temple of Cloicina. It is an example, too, in which the will is seen to exert a retarding as well as accelerating effect upon the intes-The will has a still greater control over the muscular coat of the bladder, by which that organ is excited into action in the voluntary discharge of urine (§ 518). In the foregoing cases, however, the will commonly operates upon the organic muscles through its associate action upon the muscles of the abdomen and perinæum (§ 243, 519).

Here, also, is presented another fact in proof of the exactness of Design, another display of the special modifications of the properties of life, since it is here, if any where in organic life, that the will may be instrumental in carrying out the final causes of nature, while there is no reason to suppose that the will can exert an influence on any other part of the truly organic system (§ 72-74, 136, 181½ d, 199).

500, ee. The principle concerned in the foregoing voluntary and involuntary movements is the same as when an emetic operates; only, in this instance, the peculiar impression transmitted from the mucous tissue of the stomach, through the sensitive fibres of the pneumogastric nerve, modifies and directs the nervous power in a way peculiar to itself; so that besides taking its reflected course through the respiratory nerves of motion, and exciting convulsive instead of respiratory

^{*} See p. 891, § 1077, and Note A p. 1111.

movements, it falls upon various other parts, and may thus simultaneously induce copious perspiration, establish profuse secretions from the liver, intestines, &c., and break up croup, or pneumonia. Exactly the same law, also, is concerned when other remedial or morbific agents exert their effects upon parts remote from the direct seat of

their operation. See RIGHTS OF AUTHORS, p. 912.

500, f. The foregoing analogy between voluntary and spasmodic motions, and the mixed motions of respiration, extends to those movements which are generated or influenced by the passions, and between the whole there is a close analogy with the effects of all physical agents, and all morbid states, which influence organic actions through reflex impressions of the ganglionic nervous system. The passions, also, like physical causes, produce involuntary movements in animal

as well as organic life (§ 245, 844).

500, g. Different orders of nerves are, however, concerned in the transmission of impressions, more or less, according to the nature of the exciting causes. Thus, the nerves of volition are not those by which organic processes are influenced. Even in the voluntary muscles the irritability which is relative to their organic functions, as, also, sensibility, may be morbidly exalted, and yet the muscles be incapable of obeying the will, as often happens in paralysis (§ 487, gg). Again, other muscles, as those of respiration, are influenced both through the will and by reflex nervous action. And while, in these respects, we can recognize no anatomical distinction, either in structure or relation of the parts, this inscrutable phenomenon is not less paradoxical than the agency I have ascribed to the nervous power in the production and cure of disease; while yet more astonishing is the institution of different orders of nerves, even of fibres in common nerves, for the transmission of impressions to the nervous centres, and from those centres to the circumference; and more surprising still is the reception and transmission of impressions from these centres (§ 189, 234, 450 e). And still more remarkable is the manner in which the will, the passions, and other exciting causes of motion, through the agency of the nervous power, pass over intermediate nerves, and elect, as their motor channel, those which are variously disconnected in their anatomical relations (§ 2333).* And here we may observe, farther, the analogy which subsists between the modus operandi of the will, and of physical agents, in developing motion (d). In all the cases, whether voluntary or involuntary, or mixed, as in respiration, the nervous power is roused and transmitted through motor nerves upon the irritability of all the parts that may be influenced (§ 188, 205). In the case of the will, and the passions, and of the immediate action of physical agents upon the nervous centres, the development of the nervous power is direct; but, when causes operate upon the nervous extremities, the nervous power is, of course, developed by impressions transmitted to the central parts (§ 113, 224, $475\frac{1}{2}$, $891\frac{1}{2}$ g, $893\frac{1}{2}$, 1072).

500, h. Again, we learn from the foregoing considerations, that, since the will determines voluntary motion, but has no influence upon organic actions, with the exceptions stated (e); and since, on the contrary, the passions operate powerfully in organic, but imperfectly and only in an involuntary manner in animal life, and as judgment, perception, and reflection, exert no appreciable influences in either life, unless as morbific causes, or sometimes lessening the action of the

^{*} See NOTE As p. 1131.

heart, while each manifests special relations to the nervous system, it appears that all these causes or properties are distinct elements of the mental and instinctive principle; just as irritability, sensibility, mobility, &c., are distinct properties or elements of the vital principle (§ 175 b, 183, 188½ d, 234 c, 476 c), or equivalent (§ 1067, 1072 b).

500, i. Consider, again, how different agents applied to different parts will affect particular organs, remotely situated, in a very uniform manner, and, by common consent, through the nervous system; as the respiratory muscles, for example (§ 137). "The whole system of respiratory nerves can be excited to action by irritation of any part of the mucous membrane, from the mouth to the anus, from the nostrils to the lungs." This irritation may be established, and result in increased respiratory movements, by mechanical agents, as by tickling the fauces, and by many others through their intrinsic virtues, as tobacco applied to the nose. But, what is more remarkable, respiration may be also accelerated by impressions made upon particular parts of the surface of the body, as by tickling the feet; and again, by a strong light impinging on the retina; and yet, again, by hope and fear, by love and hatred. These examples embrace all the varieties that occur between the simple act of respiration and coughing, sneezing, and convulsive spasm. Again, another modified order of movements may be induced in the same muscles by agents of yet other virtues; as from the irritation of emetics. Mechanical irritations of the throat may also determine either coughing or vomiting; and here, as with the increased respiratory movements, certain irritations of the surface, as tobacco to the soles of the feet, will excite the abdominal muscles to the act of vomiting. In this last case, however, the irritation is first transmitted, by reflex action, to the mucous tissue of the stomach (§ 504), from whence it is returned to the nervous centres, and from thence reflected upon the respiratory muscles, the skin, &c. (§ 504, 514 d, k, l).

It will be thus seen, that these various agents, acting upon different parts, give rise to analogous or similar phenomena through the medium of the nervous power, but they involve a great variety of sensitive nerves, while the motor nerves are about the same in all the

cases. This reflex nervous action is our medical calculus.

500, j. But, the foregoing complexity, which must find its solution in the attributes of the nervous power operating through its anatomical medium, is vastly increased by the coincident phenomena which may be determined by the will and by mental emotions. Thus, increased respiration, coughing, vomiting, &c., may be produced by an act of the will; grief occasions weeping and sighing; joy, laughter; yawning gives rise to yawning in another; disagreeable recollections

produce vomiting, &c.

500, k. It is readily seen that a common philosophy must interpret all the foregoing effects. The fundamental cause is the same throughout. It is every where the influence of the nervous power; but what strange variety in the remote exciting causes! Nor is this all; for the same great and simple law obtains in all voluntary movements. Let us also especially remark the parallel which exists between the determination of the will upon particular muscles, according to its own choice, and thus constantly passing over, or isolating, various motor nerves, or, yet more remarkably, sending its influences through certain branches of a compound nerve and holding in passive subjection

all the rest, and of those agents which we have just seen to extend their influence specifically to the nerves of respiration, and those of a remedial or morbific nature which, like the will, elect and avoid the nerves without reference to order (§ 2333, 492, no. 6). This astonishing phenomenon is perpetually in progress in health among all the organic viscera; and when we consider, also, how the well-trained juggler brings into simultaneous action almost every voluntary muscle, and each one in obedience to the foregoing law of elective influence, we shall readily comprehend how disease, and morbific and remedial agents, give to the nervous power the same complex direction in organic life. But even more remarkable are the various intonations of voice, and especially such as form the melody of song. Each one, every variation, whatever the succession of change, is determined by an act of volition, rousing, and determining the nervous power, with all the rapidity and mutations of thought, with varying intensity, and incalculable changes of direction, and compounded in an endless manner, upon those muscles which are the immediate instruments of the vocal apparatus ($\$ 234 e, 473 c, no. 6, 526 d).

All the effects of mental emotions are so many coincidences with the operation of remedial and morbific agents. Like the will, their effects may be limited to excito-motory nerves, but they are apt to institute reflex nervous actions; each emotion, too, acting upon particular parts according to its own particular nature (§ 500 c). Take, as an example for the whole, the coincidences between the effects of disgust and emetics. The latter irritate the gastro-mucous tissue and give rise to vomiting, as in § 500 ee. Equally, therefore, must disgust institute the same chain of causation; but by first determining the nervous influence as a nauseant upon the stomach (§,514 b, c, 1067 aa, 1072 b, 1077).

500, l. In what has been said, therefore, of the various exciting causes of motion in the respiratory muscles, alone, we have a great element by which we readily attain the philosophy of those analogous examples in which morbific and remedial agents establish changes in organs where the nervous communications with the direct seat of the morbific or remedial action may be obscure, or far less manifest than with other parts on which no sympathetic influence is simultaneously exert-And, coming also to those complex influences which hold the iris in complete obedience to the great final cause for which it was ordained, and many other equally demonstrable but intricate problems relative to the nerves, and those others which concern an unintermitting action of the nervous power in maintaining some of the most exact and obvious conditions of animal life, as seen in the permanent contraction of the sphincter muscles, we have a flood of light upon the subject which will not fail to dissipate every remaining obscurity, and establish forever an impregnable barrier against the chemical and physical doctrines and all the corruptions of the humoral pathology (§ 1072 a).

500, m. If we now consider the actions of the heart and blood-vessels both in their natural state and under morbid influences, it will be seen that no chemical or humoral dogmas can have the most remote connection with the philosophy of medicine; for here will be found a concentration of phenomena which embraces not only the physiological conditions upon which all their fluctuations that emanate from the modified states of other parts depend, but a correspondence in the phenomena, that are wholly exclusive of every interpretation which can be

rendered by chemistry or humoralism within the entire range of pathology and therapeutics, and a full confirmation of my doctrines relative to the nervous system. In the first place, then, we have seen that the motions of the circulatory organs depend upon the nervous influence, as the immediate exciting cause, reflected upon the muscular tissue (§ $475\frac{1}{2}$ – $488\frac{1}{2}$, 493 cc, 514 f), and that in consequence of this susceptibility (§ 422 b, 487 a, $892\frac{3}{4}$), and of the liability of the nervous influence to endless modifications according to its exciting causes (§ 227, 230, 894 b, 904 a, 990 $\frac{1}{2}$), that influence, both reflex and direct (§ 222 a, 227, 903, 990b), is constantly modifying the actions of the heart and arteries, as seen in the operation of multitudinous external natural causes and the multifarious effects of mental emotions, while other things, except when intermixed with the blood, fail of such influences (§ $233\frac{3}{3}$, 630 c), and of all which Chemistry and Humoralism do not pretend to make any explanation. Therefore, by parity of reason all the disturbances of the circulatory organs that proceed from affections of other parts, and all the remote effects of medicines, poisons, &c., are equally estranged from those assumptions, and in all the cases the fluctuations in the circulatory organs depend equally as in the natural conditions upon reflex or direct action of the nervous power, and as will appear (§ $687\frac{1}{2}$ -688, $694\frac{3}{4}$, 826 cc) we examine the pulse (when the heart is not diseased) for the purpose alone of ascertaining how far and in what manner the pathological conditions of other parts, or the operation of remedies, &c., may reflect the nervous influence upon the circulatory organs, and not in the least to ascertain how the blood is affected or the remedies may be absorbed—See § 829, 1088.*

500, n. Contrasted with the foregoing should now be stated the doctrine of the chemical school, as it comes applauded from the laboratory. The source of motion with this school, voluntary and involuntary, is the same with that which Liebig assigns for thought, namely, a chemical change in the substance of the organ (§ 350, nos. $5\frac{1}{2}$, 7-10). In this way, too, the chemist expounds the balance between waste and nutrition; and for this purpose sleep has been ordained, the approved phi-

losophy of which is the following:

"Now, since in different individuals," says Liebig, "according to the amount of force consumed in producing voluntary mechanical effects, unequal quantities of living tissue are wasted, there must occur in every individual, unless the phenomena of motion are to cease entirely, a condition in which all voluntary motions are completely checked; in which, therefore, these occasion no waste. This condition is called sleep. Now, since the consumption of force for the involuntary motion continues in sleep, it is plain that a waste of matter also continues in that state; and if the original equilibrium is to be restored, we must suppose that during sleep an amount of force is accumulated in the form of living tissue exac'ly equal to that which was consumed in voluntary and involuntary motion during the preceding waking period."—Liebig's Animal Chemistry.

I have quoted the foregoing on account of its appearance of a rational philosophy and logical method, but apprehend that it has no better foundation than the gaseous doctrine as presented in § $350\frac{1}{2}$ n.

500, nn. But again, I ask the chemist for the primary cause of those chemical changes in which originate the acts of the mind, &c., and which call us from the sleeping to the waking state (175 c, 249 e,

^{*} Also, § 481, 494, NOTE LL p. 1140.

350³/₄ gg). I ask the chemist, and the physical philosopher of life, to explain the mechanism and the laws of sympathy by the application of any principle in physics or chemistry. Let the chemist consider, that in every process of remote sympathy there are involved very diverse, yet very precise effects, and that he must have one species of chemical change for the transmission of impressions through the sensitive nerves to the nervous centres, another for the impressions exerted upon those centres, another for the reflection of the influences through the motor nerves, and yet another for the effects exerted at the ultimate destination of this amazing round of never-ending influences, as indispensable to the process of respiration; and coming to morbid states, there must be another series of chemical changes conforming, respectively, to the nature of every morbid influence and

product (§ 188½ d, 464, 451 f, 649 b, 675, 487 gg, 1076).

Take any single attribute of the nervous system, and we shall find it as remarkably distinguished from all things else as is the mental The power which appertains to that system, and presides over the whole life of animals, is just as unique in all its operations. The distinction alone, in various aspects, between the condition of the sensitive nerves, or the sensitive fibres of compound nerves, and those which are appropriate to the motor influence,—those which convey impressions to the central parts and those which transmit them to all parts of the organization, to the organic structure of the fountain itself,—those, I say, which serve to awaken the mind, or to stamp on the nervous centres, with all the precision of thought, an inconceivable variety of influences which are unceasingly in progress in every other part, but with no other appreciable result than the movements which follow in all the organic constitution, contrasted with the totally distinct prerogative of those nerves, and those fibres of compound nerves, which give rise to the distant movements and changes, -place, at an unutterable distance, all analogy with the recognized imponderable substances and with every other agent or power in the mineral kingdom (§ 451 c, 453). But, I would not so far speculate upon the nature of the nervous power as even to assume for it a place among the imponderables, which the physical philosopher, upon no better evidence, unhesitatingly avows as the condition of light, heat, and that more inscrutable substance, imponderable magnetism, which awakens no sensation, and produces no effect upon organic life. Least of all would I place the principle of life, or its element the nervous power, upon a par with the imponderables in their designated condition as material "fluids," nor claim for the latter a distinct individuality (§ 175, bb). The true physiologist attempts not problems which have no relation to principles and laws, and which divert philosophy from its practical uses. It is true, he argues the existence of the principle of life, its remarkable attributes, its contradistinction from all other agents, upon the ground of the philosopher in physics, that he may meet the obtruder with his own ratiocination. He tells him that his premises are the same, only more various, distinct in their nature, and more demonstrative. He points him to his "undulations" of light, the velocity of their movements, the prismatic analysis, its confirmation by life, his imponderable mystery which spans the globe, its co-operation with the electric fluid, their instant transmission of a disturbing cause to the ends of the earth, making the record at one

of its poles ere the impulse has ceased which began at the other (§ $175 \ bb$, $188\frac{1}{2} \ d$, $234 \ c$, d, e, 281, $872 \ a$, $892 \ b$, $892\frac{1}{2} \ v$, $893 \ q$, $904 \ a$).

500, o. Let us now observe, summarily, the wonderful system of analogies which Nature has ordained among the vital stimuli, and learn from this, and from the same system of relationship which distinguishes other parts in the great chain of existences, that her laws are simple where the phenomena are various and complex, and that all her designs and operations are susceptible of reduction to a few general principles, which, when once known, illuminate the darkest labyrinth, and serve us instead of the voluminous facts which have been gradually accumulating for ages. One principle is a key to a thousand phenomena; and as new ones spring up, having analogies with such as are known, the principle comes to their ready interpretation.

In respect to the analogies among the vital stimuli, the mind, being connected with the body, and acting upon it both directly and through the nervous power, should naturally be one of them; and here we find it operating in peculiar ways upon the irritability both of organic and animal life,—first directly upon the brain, and then producing voluntary motion through the nervous power, or so affecting the organic states as to be a morbific or a curative agent. Just so with foreign agents. Irritate the brain and spasms will follow, while the same irritation goes to the recesses of organic life. The natural stimuli of life maintain the vital actions by exciting the vital properties. But, there are many foreign agents which are morbific, and these operate in the same way, only, at the same time, they alter the nature of the vital properties; and it is exactly in this way, also, that the mind and its passions produce disease. The impressions, however, in the former case, may be reflected from the nervous centres, while in the latter, they originate in those centres. Again, there are other foreign agents which aid in restoring the diseased properties and actions to a healthy state, and their principle of operation is exactly similar to that of the mind when this agent aids in the removal of disease (§ 1067).

Take next the blood, the natural vital stimulus of organic actions, which makes its impressions upon the same properties and develops the nervous influence like the mind and foreign agents. But, unlike the latter, it is a living agent, and calls into action the properties of life for the purpose of being itself acted upon, that it may be incorporated with the organized structure and receive the plenitude of those powers through which it becomes a part of the organized tissues, that this new formation may again generate the same fluid, and be acted upon, in its turn, by other blood. Its analogy, therefore, to the mental principle relates especially to its property as a vital agent. But, we find in the nervous power an agent of more extensive analogies with the blood, since this agent, like the blood, not only affects the organic properties and actions, but is also exquisitely susceptible or modifying influences, of changes in its nature, from the action of the mind and from external morbific and remedial agents, -acquiring even the very character, as an operating cause, which appertains to the agents, respectively, that may call it into action (§ 223-232). range of analogies is, therefore, coextensive between the nervous power and all other vital agents (§ 74 a, $188\frac{1}{2}$ d). And so of the semen in its action upon the organic properties of the ovum; infusing, also, not only a physical, but a mental constitution into the ovum. The

corporeal and mental attributes of both parents are, in consequence,

blended together (§ 63, &c., $475\frac{1}{2}$).

Consider, finally, the hibernating animal, whose general medification of irritability (§ 191) is so constituted with a reference to preservation against low degrees of external temperature, that mechanical irritation, heat, and a variety of agents applied to the surface, shall so awaken the nervous influence that his temperature will suddenly rise from below the 40th degree of Fahrenheit up to its natural standard of 98°. But the curious fact attending this remarkable law of preservation is the same result from an intensity of cold that would otherwise

destroy the animal (§ 441, d).—Note AA p. 1131.

500, p. In respect to the subserviency of the brain to the operations of the mind, I will add in farther explanation of what I have said in section 241, that we have the best reasons for believing that the brain is especially designed for the subserviency of the will and perception, and has comparatively little connection with judgment, reflection, &c., and less with perception than with the will. Its great final cause, in respect to mind and instinct, is to serve as a medium of communication with the voluntary muscles, through the nervous power (\S 455, a). The will is, therefore, a stimulus to the brain, while this organ supplies, in consequence, the nervous power by which the voluntary muscles are brought into action.

In respect to perception, we discover the relation of the mind to the brain in another aspect, and, also, another analogy between the will and physical agents as vital stimuli. Through sensibility the brain is acted upon, and this impression rouses the mind, or its property, perception, and sensation is the resulting effect (§ 175, c).

501, a. Sympathy is active when it produces sensible effects. It is passive when its effects are insensible, as in the natural rhythm of the organic system. It is either reflex or direct nervous action (§ 638½).

501, b. In the perfectly natural condition of sympathy in organic life the nervous influence is a mere regulator of the organic properties. Its natural operation is disturbed by morbific and remedial

agents, and by mental emotions.

501, c. It is mostly in conditions of disease that we notice the results of sympathy. In health we see only the universal harmony; unless disturbed by a blush, or by the abundance of urine when cold chills the surface, or fear exerts its more mysterious sway. Disease affords the striking examples of display in the nervous power, and these examples are what most engage the attention of the physician. To trace out their complexity, as one part after another gives rise to disease consecutively in each, and as each may exasperate the morbid states of the whole, or as remedial agents may institute corresponding circles of reflex action, are the most important and difficult objects of medicine.

502, a. Diseases generally begin with little agency of the nerves. Morbific causes make their impression upon the vital constitution of some particular part, when it commonly happens, sooner or later, that the affected state of the part is felt by the nervous centres, from whence a disturbing nervous influence is transmitted to other parts (§ 133-154, 188-193, 516, no. 7, 657, 666).

502, b. In all the foregoing cases, therefore, where remote parts become the seats of morbific action, as in pneumonia and idiopathic fever,

sympathetic sensibility is affected by the primary morbific cause as an important element in establishing the remote predisposition (§ 149,

201, 451 b, 559, 660, 666).

502, c. Remedial agents may operate directly upon a part and restore its morbid properties and functions without reflected nervous action. This is apparent only where the remedy is applied directly to the tissue affected; but, in all other cases the nervous power is the medium of transmission. Upon these fundamental principles, the main art of therapeutics is or should be founded (227, 644-647½).

503. When disease, or morbific, or remedial agents transmit their influence from any part to the brain and spinal cord, and there develop and modify the nervous power, the modification corresponds with the nature of the impression which is transmitted to the nervous centres. These transient modifications of the nervous power are similar, in principle, to the changes which occur in the organic properties, and which essentially constitute the disease. The passions also modify the nervous power in ways peculiar to each; and, in all the cases. corresponding effects are produced upon the condition of diseased parts upon which the nervous power thus modified may be reflected. That is to say, the nature of the nervous power is variously modified in all the cases; and, therefore, like external morbific or remedial agents of different virtues, modifies the vital states according to its own acquired modifications. The nervous power, therefore, thus acquires, more or less, the virtues of the exciting causes, and becomes, more or less, a substitute for them (§ 226).

504. Various circles of sympathy are generated by the action of remedial agents upon the stomach, intestines, &c. The first impression of the agent may set in motion a great range of reflex nervous actions; as the operation of emetics (§ 500, i); and, as new impressions are sympathetically instituted they become the points of departure for other reflex nervous actions, and react upon and increase those

in which they originate.—Note D p. 1114.

505. When the nervous power is excited by remedial agents of positive virtues it is essentially morbific, like the remedial agents themselves. Each is, therefore, curative only by inducing new morbid conditions by which the natural recuperative tendency of the vital properties is brought into operation. The great difference is, that morbific agents alter the vital conditions more profoundly and more permanently than the remedial (§ 854 c-858, 893 d, e, 894 b-901).

506. Impressions once made upon any part may continue for an indefinite time after the cause is withdrawn, and may continue to develop and modify the nervous influence, and direct its operation upon other parts, as when the agent was in operation (§ 516, no. 6). Thus, the operation of many active remedial or morbific agents will continue to be exerted upon the system at large, for a longer or shorter time, after they shall have been thoroughly removed from the stomach, &c. Inflammations excited by cantharides, issues, wounds, &c., hold an unceasing operation, curative or morbific, upon remote parts. The specific impression made by the virus of the mad dog becomes established in the bitten part, and generates a morbific reflex nervous action till, through the law of cumulation, an explosion of disease ultimately follows (§ 558, a). The same principle, exactly, is applicable to mercury, when a small dose, or its external application, produces saliva-

tion, or when miasmata give rise to fevers in a month, or six months after their direct operation has been withdrawn. The principle is constantly illustrated in natural states of the body; as where the sphincters remain permanently contracted after the expulsion of the urine or of fecal matter (§ 514 g, 516, no. 6, 1059).

Here, then, we have another important law to interpret the true

modus operandi of remedial and morbific agents (§ 503).

507. The nervous power pervades the whole system of motor nerves; and, although its active operation in the ordinary function of sympathy be developed mainly, if not altogether, in the central parts, it may be brought into operation by irritating any of the motor nerves (§ 473 c, 499). A division, or other injury of nerves going to the organic viscera, as the par vagum, may destroy their functions, or otherwise affect the vital constitution and products of the part, or induce inflammation, by the shock of nervous power thus inflicted on the organic properties of the part (§ 461, 485, 489, 950, 1032 d).

508. The nervous systems are as liable as other parts to be affected in their organic condition by the nervous power, which, in the same way, may be actively determined upon them. But, there is this difference. When any part of the nervous system is the seat of disease, it is liable to produce greater disturbances in remote parts than other organs when diseased. These disturbances are occasioned by the direct propagation of the nervous power, but they are apt to be less of a morbid nature than when produced by the more complex

process of reflex action (\S 500, a-c).

509. The nervous power may extinguish life with great instantaneousness. When rapidly fatal, the causes by which it is brought into operation must be violent and sudden in their action (§ 455, d). Examples occur in the fatal effects of joy, anger, blows on the epigastric region, drinking cold water, prussic acid, sudden death from small

losses of blood, apoplexy, &c. (§ 479, 1040).

In the case of joy, anger, and apoplexy, the nervous power is developed in a direct manner (\S 500, c), and destroys mainly by its sudden determination upon the organic properties of the brain and heart. Blows on the stomach give the same determination through reflex nervous action, as do also cold water and prussic acid (\S 476 $\frac{1}{2}$, h). The mode of death from small losses of blood will be explained under the philosophy of the operation of its loss (\S 943, 946, &c.).

In the foregoing cases, the nervous power is also determined with violence upon the stomach and intestines, and upon the whole capillary system of blood-vessels (§ 481, &c., 490). The general effect is

also increased by the injury sustained by the brain itself.

510. The foregoing modus operandi of the several agents is similar to the causation of sudden death from injuries of the brain or spinal cord. Thus:

If the spinal marrow be suddenly destroyed, or only one half of it, by a large stilette, life is immediately extinguished. The modus operandi appears to be the following:—1st. An injury of the vital properties of all the organic viscera. 2d. A violent interruption of the concert of organic actions. 3d. An interruption of respiratory movements. 4th. A pernicious nervous power is propagated from the cord to the organic powers of the brain. 5th. Pernicious influences are propagated by the organic viscera to the cerebral and ganglionic sys-

tems,—thus greatly increasing the destructive nervous influence upon themselves (§ 455, c). They are complex circles of nervous influence, but are determined by exact laws, and each circle has its distinct individuality, although involved in each other.

A like explanation is also applicable when a sudden destruction of

life is effected by crushing the brain.

511. It is upon the principle that the effects of the nervous inffuence depend upon the exact nature of the impressions made upon the nervous centres, whether direct or indirect (§ 226, 500), that we must explain the differences in the results of slightly-varied experiments relative to these parts; those, for instance, by which the brain or spinal cord is slowly destroyed interrupting the harmony of actions and the organic functions more gradually, and therefore less fatally, than such as produce their destructive effects with greater rapidity.

V. THE LAWS OF SYMPATHY, OR REFLEX ACTION OF THE NERVOUS SYSTEM, AND THEIR APPLICATION TO PATHOLOGY AND THERAPEUTCIS.

General Facts and Laws relative to the Cerebro-spinal and Ganglionic Systems.

512, a. The various nervous communications of the intestinal canal with the brain and all other organs are demonstrative of the ascendant influence which the stomach, particularly, possesses when acted upon by remedial agents. We see all this exemplified, analogically at least, in the endless remote derangements which follow the common irritations and morbid states of the organ, as, also, of the intestines. We see, indeed, the whole in natural progress. When, for example, hunger operates, an actual sensation is then felt by the brain, and the mind, of course, participates (§ 323). Numerous and complex influences may be thus brought into operation, of which the stomach is the primary source. The will, being excited, brings into action all those muscles which are necessary to obtain a supply of food, and other muscles to effect its mastication, and convey it to the stomach. Various sympathetic organic influences are, in the mean time, taking place, which it is unnecessary, as it might be difficult, to explain. Many of these organic influences spring from the mind itself. Thus, the brain feeling the sensation of hunger, the salivary glands begin to pour out their fluid at the sight or smell of food, or even at its expectation. The food establishes an influence upon the nervous centres, by which an exciting nervous power is constantly reflected upon other parts. The bile, saliva, &c., are thus increased, while the mind contributes a direct nervous influence towards these results. The stomach being supplied with its wants, all these influences cease, and a new order arises. Cut off the par vagum and none of them will obtain, unless feebly through the ganglionic and spinal nerves. When the food has undergone digestion, and the exciting impression is removed from the stomach, all the reflected influences of the brain and spinal cord cease in consequence.

512, b. The vascular action and the glow of warmth, which are lighted up in the skin of the fasting, half-frozen traveler, and his invigorated strength before digestion has made any advances, and the flow of bile which is determined by the action of food on the stomach, especially where the food is of an animal nature, are manifestly

owing to an exciting reflex action of the nervous system; or, again, the copious perspiration, and other results, which often follow immediately a draught of hot water, illustrate the whole philosophy of this apparently entangled subject of sympathy, whether in relation to natural, morbific, or remedial agents; and we learn from these obvious examples that the essential principle is simple, and readily explains all the diversified phenomena, which are effects of reflex and direct nervous actions, whose original starting point is the gastro-intestinal mucous membrane. But when, in the case of the food, it shall have been digested, and have entered the circulation, some of its earliest and strongest demonstrations may have disappeared. It is worthy of remark, too, that such is often the immediate effect of food upon the great nervous centre, that sleep is almost irresistible, or apoplexy follows, "paulo post prandium," as no unusual result; the nervous power being reflected, in the former case, upon the organic properties mildly and agreeably, in the latter with sudden and destructive violence (§ 226-233, 441 c, $476\frac{1}{2}$ h, 500-511, 1040).

513. Physiological conditions, like the foregoing, are so intelligible as to be peculiarly important in illustrating coincident problems in pathology and therapeutics. Whenever well-pronounced reflex nervous actions are propagated from one organ to others through the cerebro-spinal and ganglionic systems in their natural states, and by natural stimuli, as by food, these influences are generally greatly increased, as well as modified in kind, by morbific and by remedial agents

(§ 524, no. 1).

514, a. The foregoing considerations lead me to the statement of one of the most important laws in physiology, which is alike applica-

ble to the cerebro-spinal and ganglionic systems, namely:

"When impressions, made by the action of external stimuli on sensitive nerves, give rise to motions in other parts, these are never the result of the direct reaction of the sensitive and motor fibres of the nerves on each other. The irritation is conveyed by the sensitive fibres to the brain and spinal cord, and is by those communicated to

the motor fibres" (§ 455, 462-472).—MÜLLER.

The foregoing law is in operation in all cases of remote sympathy, whether of a physiological, pathological, or therapeutical nature (§ 455, c-h). It is clearly exemplified in the natural process of respiration, by the analogous results of emetics, &c. In respiration, the want of air is felt through the medium of the sensitive fibres of the pneumogastric and sympathetic nerves, and appears to be concentrated about the medulla oblongata. The nervous power is thus developed, and is then reflected upon the various motor nerves which supply the muscles of respiration; when the action of these muscles follows as a consequence (§ 233, 462-472, 500).

514, b. The only remarkable difference in the physiology of vomiting from that of respiration consists in the primary impression being made upon the same nerves in the mucous tissue of the stomach, and the convulsive movement of the abdominal muscles. A radical difference, however, obtains in the influences which may be exerted by an emetic upon the organic states; especially in their diseased conditions. This, too, will depend greatly upon the cause of vomiting; and so of every other agent, according as it may be natural, morbific, or remedial. When the effects depend upon reflex nervous influences,

^{*} A term of frequent occurrence among Authors who wrote in Latin.

the morbific and remedial agents so modify the nervous power that it alters the existing condition of the organic properties and functions of all parts upon which its positive action may fall (§ 129, 226, 227).

If the stomach itself be the seat of disease, even its mucous tissue, the remedial effect of any agent may not be wholly, or principally, due to its direct action upon the organ, but may be also exerted through a chain of causation exactly similar to that by which the respiratory muscles are thrown into action in respiration or vomiting. This must be obvious enough in the case of peritoneal disease of the stomach; and it is equally true of diseases of its mucous coat, that the impression of the remedy is transmitted, more or less, through the sensitive fibres of the pneumogastric and ganglionic nerves to the brain and spinal cord, when the nervous power is reflected, with an alterative effect, through the motor fibres of the same nerves upon the mucous, as upon the serous, tissue of the stomach. The same philosophy applies to the muscular coat of the stomach in the action of an emetic, and to the same tissue of the intestines when peristaltic movements are excited by cathartics (§ 657 a, 658, 889 a, 902 g).

Again, the bile which is ejected during the action of an emetic or a cathartic may have been mostly generated under their influences; the emetic or the cathartic establishing a bilific reflex nervous action over the liver, in conjunction also with continuous sympathy (§ 498); and those influences, in connection with the more efficient direct irritation of the intestinal mucous tissue, instituting the increased product of that membrane. These palpable facts associate themselves with the immediate exciting cause of the muscular movements in vomiting and defecation, and with an endless extent of analogous results that flow from other unusual influences, and thus evince the dependence of the whole upon the foregoing causations, of which alterative reflex nervous actions are apt to be the principal.

514, c. We thus comprehend how an emetic of the most simple nature may suddenly arrest a paroxysm of hooping-cough, or of spasmodic asthma, or of hysteria. The emetic, through the foregoing process, induces new movements in the affected muscles, and thus ends the paroxysm. Dr. Greenhow, for example, has lately related, in the London Medical Gazette, the case of a man, who was affected with a choking, as if a ball was rising in his throat, and shortly after a violent hiccough began, which continued for several days. About the eighth day, his wife, sister, and maid-servant, "got into the same state;" the affection being communicated in the last three cases or induced by the operation of the mind (§ 227, no. 1, 844 a). "It was a painful spectacle, though a somewhat ludicrous one, to see four individuals all hiccoughing at the same time." Opium, valerian, asafætida, camphor, magnesia, &c., failed entirely of affording relief. "However, something taken by the maid-servant made her vomit, and from that moment the complaint ceased. A mustard emetic was immediately ordered for the others, when the sister and wife were also relieved; but not so the husband, whose attack, however, was always suspended by vomiting, but soon returned." In the case of the husband, there was present a state of disease, which continued to reproduce the paroxysms; but in the other three there was little else than the spasmodic action of the muscles. Dr. G. says he "always afterward found that vomiting put an end to attacks of hysteria, and believes that the dread of an emetic has often had the effect of checking

an hysterical attack;" in which case the mind develops a controlling nervous influence.—Note Cc p. 1132.

514, d. Consider, next, an example of the manifestation of sympathy between the skin and other parts, as indicative of the modus operandi of remedial and morbific agents when they establish their influ-

ences upon distant parts through the medium of the skin.

Volkmann, in pointing out the great difference between the trunks and the minute terminations of the nerves in the power of exciting reflex motions, prefers the skin for illustration; which, he says, surpasses all other organs in the property of exciting these motions. When an animal, for example, is under the influence of opium, the slightest touch of the skin is frequently sufficient to give rise to strong spasms, while reflex actions excited by irritating the distinct nerves of the skin are generally less. The philosophy is the same when cold air, or cold water, restores a patient from a state of syncope. A drop of cold water, when snapped upon the face, rouses the subject by transmitting an impression through the cutaneous nerves to the nervous centres, which instantly develops an exciting nervous influence that is then reflected upon the muscles of respiration, and upon the heart and extreme blood-vessels. The same law governs, also, the constant mutual interchange of action between the skin and alimentary canal, the skin and kidneys, &c., whether in health or disease. From these examples of a great fundamental law, we readily obtain the modus operandi of mercury, iodine, blisters, issues, &c., when applied to the skin, and of cold in reducing hernia (§ 224, 232, 527 b, 1088 b, c).

514, e. With the qualifications stated in sections 458, 459, it is "a general law, that, whenever general spasms are excited by local impressions, the phenomenon depends on no other communication between the sensitive and motor fibres than exists in the spinal cord. In many cases, however, local irritation of the nerves gives rise, not to general, but to local muscular spasms." "In the contraction of all the perineal muscles in expelling the semen, which are excited by irritation of the sensitive fibres of the penis, the spinal cord is the medium of communication between the sensorial impressions and the

movements."-MÜLLER.

514, f. Many "muscles invested by sensitive membranes, and are not themselves exposed to the direct stimulus, can only be excited to action by irritation of the sensitive property of their investing membrane, the transmission of this irritation to the nervous centres, and the propagation of the motor influence from the nervous centres to themselves. Thus, the contractions of the glottis and air-passages, excited by the contact of irritating gases, are not the immediate result of the irritation of the parts themselves, but of the excitement of the sensitive fibres distributed to the mucous membrane and the reflected influence of the brain and spinal cord upon the motor nerves of the muscles. The movements of deglutition belong to this class. stimulus of the morsel in the fauces excites the act of deglutition. In this case, the sensitive nerves which transmit the impression to the nervous centres are, according to Dr. Reid, the glosso-pharyngeal, the superior laryngeal, and the branches of the fifth, sent to the soft palate and isthmus of the fauces. The motor nerves for the movements of deglutition are the pharyngeal branches of the par vagum. A like explanation applies, also, to the irritations of the sphincter ani and the sphincters of the bladder. The muscles cannot be themselves stimulated by the excrement and the urine; but these matters act upon the sensitive nerves of the mucous membrane and excite the spinal cord, which, as if constantly charged with motor influence, reacts upon the muscles. In this case the phenomenon appears to depend on no other communication between the sensitive and motor fibres than exists in the spinal cord. Hence, after injury of the spinal marrow, these

sphincters become relaxed."-MÜLLER.

The operation of cathartics involves more complex laws. These are agents of specific virtues, and are capable of modifying the vital states of the intestinal canal and of parts remotely situated. Their direct impression is exerted upon the intestinal mucous tissue; but the muscular is brought into increased action both by contiguous and remote sympathy (§ 497). This renders it manifest that reflex nervous action is concerned in the ordinary peristaltic movements that are induced by the natural contents of the alimentary canal (§ 475\frac{1}{2}, 490); nor, indeed, is it conceivable that either the intestinal muscular tissue or that of the heart can be reached in any other way than by the stimulus of the nervous influence excited as in § $475\frac{1}{2}$, 490. But in the case of cathartics, something more happens. The influence being extended to the nervous centres, the nervous power is propagated through motor fibres of the pneumogastric and sympathetic nerves upon the intestinal mucous tissue, by which the various influences of these agents are increased, as in the experiments by Wilson Philip (§ 113, 224, 226, $475\frac{1}{2}$, 491, 889 a, 1042, 1088 d).—Notes A p. 1111, B_B p. 1131.

514, g. The sphincters remain contracted after the expulsion of the fæces and urine. This is owing to the permanence of the impression upon the mucous tissue, which maintains an excitement of the nervous influence till the excrements are again deposited. And so of the continued influences of remedial and morbific agents long after the agents themselves have ceased to operate; the impressions remaining upon the parts where their direct action had been exerted. In this way miasmata, the virus of the mad dog, mercurial and other remedies which may be slow in the full development of their effects, establish their influences where their direct action may fall, and these are subsequently and slowly propagated to other parts by unceasing alterative reflex nervous actions (§ 516, nos. 2 and 6, 578 d, 657 a). See also roosting (§ 500 dd).

514, h, More complex examples of the law with which this section was begun will be presented hereafter. Such as have been stated are intended as introductory to the series of laws which are soon to follow. But we see from examples already produced, that when sympathies are set up in one part they may become the cause of sympathies in other parts, and that in this manner remedial and morbific agents, which begin their action on some given part, may establish very complex sympathetic effects, each modifying the others through new influences upon the nervous power (§ 228). When the food, for instance, as in § 512, induces vascular action and warmth in the skin before digestion commences, that organ excites salutary reflex nervous influences on the digestive organs, and thus promotes digestion. When tartarized antimony, in small doses, induces a sudorific nervous influence, the skin becomes the source of many reflex nervous actions upon other organs; thus showing, also, that it is not the perspiration, but the vital change in the organ itself, which leads to results that can-

not be imitated by any other mode of exciting this excretory function And so, more or less, of other parts upon which the antimony may

exert its primary sympathetic effect (§ 863, e, 902 g).

Thus it happens, that whether certain remedial agents are applied to the stomach or skin, reflex nervous actions are propagated to each, as well as from each to other organs, while each, in its turn, reflects the impressions back to the brain and spinal cord, from whence they are again returned with increased intensity; or organs not before involved are ultimately brought under their influence (§ 129 \hbar , 674 d). And so of disease of any given organ; which is only equivalent to the influences of morbific causes (§ 647, 660).

If two or more remedial agents be united, it is readily seen that their combined effect may be extended from the stomach to various parts of the body, and thus other alterative reflex actions propagated among themselves, and variously determined upon other parts (§ 872 a).

514, i. We may now regard an example which presents a union of the physiological, pathological, and therapeutical principles, as set forth by myself, in their relation to the nervous influence; all referable to one common law in its connection with modifications of the nervous power (§ 226). Thus: "Certain cases," according to Marshall Hall, "as hydrophobia, epilepsy, hysteria, and certain remedies, as strychnia, cantharides, &c., not only induce augmented excitability, but manifest their effects upon the organs which are physiologically under the dominion of the excito-motory power."

514, k. Finally, a glance at the physiology of the contraction of the iris may aid our understanding of the complex sympathetic influences of morbific and remedial agents, and of the applicability of the following physiological laws to the modus operandi of such agents.

It is first worthy of observation, that the iris may be pricked with a knife without exciting contraction, while it is exquisitely sensitive to the action of light (§ 74 a, 188½ d, 136, 137). The co-operation of a sensitive and motor nerve, through the medium of the brain, is necessary to this phenomenon. The impression upon the retina, being transmitted to the brain through the optic nerve, is reflected upon the iris through the motor ciliary nerve. This may, perhaps, open the eyes of the chemist as to the true doctrine of vision (§ $188\frac{1}{2}d$, 500 nn). But it is a more interesting fact, that when one eye is closed, and the other open, the pupil of the closed eye will follow, in a measure, the movements of the open eye; and this will happen to an amaurotic eye when the sound one is exposed to the stimulus of light. This sympathy between the two eyes, as well as in other respects, and the harmony between the two ears, involve very delicate considerations as to the influences of the nervous centres, and may be employed in tracing out the philosophy of many obscure interchanges of action among different organs, either in their natural states, or when they are disturbed by morbific or remedial agents (§ 1072, a, note).

514, l. A multitude of illustrations may be brought to the same purpose, which show us, also, how complex may be the influences of morbific and remedial agents, and how the mind may participate, when these agents operate upon the organic properties which conduct the insensible movements. Thus, sneezing is commonly produced by the action of stimuli upon a nerve of common sensibility distributed from the fifth pair to the mucous tissue of the nose, and the

reflection of this irritation upon the respiratory nerves. But the stimulus of the sun's light may produce sneezing by acting first upon the optic nerve, and through that medium upon the nervous centres. The nervous power thus developed is reflected upon the Schneiderian membrane through the branches of the fifth pair which impart common sensibility to the nose (§ 198). Here a new sensation arises, which is sent back to the brain and spinal cord, the nervous power again developed, and, according to relations between that membrane and the respiratory organs, and the nature of the remote cause, the nervous power is now reflected upon the respiratory muscles, when sneezing follows as the result of the convulsive movement. (See, in connection, § 188½ d, 500 nn).

The mind itself will do the same thing by dwelling intensely on a former paroxysm of sneezing. Here the nervous power is excited in a direct manner by the mind, and is then, as in the foregoing case, directed upon the nasal branch of the fifth pair. And so of sympathetic yawning, sympathetic micturition, vomiting from disgust, &c.

514, m. The olfactory nerve is mostly endowed with specific sensibility, and is only excited by odors, while they have no such effect upon the nasal branches of the fifth pair, unless the odors be at the same time of a pungent nature; and then it is the pungency, not the odor, that operates. Odors affect the mind agreeably or disagreeably. The smell of a rose may have no other effect than that of so impressing the brain as to give rise to a pleasurable sensation. But, in some constitutions its impression will excite a variety of reflex ner-Its effect may be at first pleasurable, but followed vous actions. immediately by the transmission of a disturbing influence to the heart, or stomach, or even to the intestines. The heart may be thus depressed in its action, the stomach nauseated, and the bowels have been purged by the same cause. Hence the poet's expression, to "die of a rose in aromatic pain." Even the recollection of disagreeable results from offensive odors brings on nausea and vomiting (§ 500, i, k. See, in connection, § 188½, d).—Note D p. 1114.

Laws of Action of the Sympathetic Nerve, and the Propagation of Impressions in it.

514½, a. Having now, and in former sections (§ 471-475, 477-496, 500), stated the most important facts and laws which relate to the cerebro-spinal system, whether acting independently, or in connection with the sympathetic nerve, I shall proceed to speak of those which concern especially the latter system. But the cerebro-spinal is so interwoven with the sympathetic nerve, it is obvious that the influences which appertain to the brain and spinal cord must be more or less common to the ganglionic nerve (§ 115, 458-460, 893 a).

514½, b. The following laws are generally inferable from what has been already said of the nervous power, and of sympathy. But, I have deemed it most useful to the young student of medicine, and possibly to the more advanced, to present them in a brief and systematic form, with comments of a practical nature. The quotations are from Müller, unless otherwise stated. In this branch of physiology Müller is eminently philosophical; and in thus adhering to the path of nature, he is arrayed in opposition to those chemical and physical views with which he has thought proper to obligo the mate-

rialists of the age, and which prevail in other parts of his work on Physiology. After variously expounding the laws of the vital principle, and reasoning as a philosopher upon the abstract subject of reflex nervous influence, like Marshall Hall, and others, he cuts loose from all analogies, and from the whole philosophy of the vital properties. As in the equally remarkable case of Wilson Philip, he ascribes all the organic functions and products to physical and chemical agencies,—maintaining that,

"The formation of any one of the peculiar secretions, the essential proximate constituents of which do not exist in the blood, presupposes the operation of a special chemical apparatus, whether this be a membrane or a gland." Of all morbid states, he affirms, that "All these phenomena are owing to a noxious matter absorbed into the blood, or

generated in it."

The same humoral interpretation is applied to the modus operandi of remedies, which, like morbific agents, are supposed to be taken into the circulation by endosmosis or by capillary attraction, and it is quite "uncertain," he says, "whether the matters are first received into the blood-vessels or lymphatics."—MÜLLER'S Elements of Physiology. Also, Medical and Physiological Commentaries, vol. i., p. 37, note, 56, note, 565, 570, 684, 685; and this work, § 494, dd.

I have thus adverted again to the discrepances in the views of this philosopher, that the reader may appreciate the value of his luminous exposition of the laws of sympathy, since they contemplated no theo-

retical conclusions in pathology or therapeutics.

515. It is still a controverted question how far the sympathetic nerve is independent of the brain and spinal cord, though in their natural state the intimate physiological relations of the latter to the former admit of no doubt (§ 459). Microscopical investigations have been carried on extensively with reference to this inquiry by Valentin, Volkmann, Bidder, Müller, Remack, Henlè, Purkinje, Rosensthat, Pappenheim, and some others less known in the walks of physiology. As may be readily supposed from the nature of the investigation, and the means relied upon, there has been great discrepancy, and even entire opposition, in the principal statements and conclusions; all tending to strengthen my objections to the use of the microscope in anatomical and physiological inquiries (§ 131.* Also, Med. and Phys. Comm., vol. i., p. 699-712; and Examination of Reviews, in vol. iii., p. 6, 89).

We know enough, however, of the relations of the sympathetic nerve and cerebro-spinal systems, and of their connections with other parts, and enough of the phenomena which grow out of those relations, to lay down the important laws of sympathy; and these are

what we require for practical purposes.

Of the Actions of the Sympathetic Nerve in Involuntary Motions.

516, a. 1. "All the parts subject to the influence of the sympathetic nerve are incapable of voluntary motion," except as in § 500 e.

2. "The parts which are supplied with motor power by the sympathetic nerve still continue to move, though more feebly than before, when they are separated from their natural connections with the rest of the sympathetic system, and wholly removed from the body."

This is an important fact, as contributing to prove that the viscera of organic life obey not only the nervous power, but other stimuli, and

* Observations have become more accurate and greatly multiplied, but the essential objections remain, as in most other physiological processes.—1860.

that all the essential processes are carried on by properties peculiar to themselves (§ 184, 188, 205-216, 222-232, 475½, 476-492, 494, 500),

though constantly influenced by the nerves (§ 456 a, 746 c).

516, b. Clear demonstrations of the foregoing law abound in the history of organic life. That in relation to the extirpated heart, where the air and mechanical irritants were equivalent to the nervous stimulus, illustrates the subject (§ 264, 498 e, 637).

516, c. Again, if the intestines be removed from the body, and some part of them irritated, their motion is increased, "and this effect continues long after the stimulus is withdrawn, and does not immediately attain its greatest degree." And so with the heart. Its contractions may not begin till some seconds after it is irritated, and they may then be long continued (§ 516, nos. 6 and 7). This does not show, however, that the nerves do not supply the natural stimulus of the muscular tissue, but only that other stimuli will excite its action (§ 475½, 478 b, 490).

516, d. We have, therefore, in these examples, a type of all the movements which arise from continuous sympathy* (§ 498, 524, no. 2), and a proof of the existence of the organic properties, of their independence of the nervous system, and of the active, vital nature of the dilatation of the heart (§ 498 e). The principle is of great moment in a pathological and therapoutical aspect. We see, for example, that the direct facts, and the analogy supplied by the active dilatation and contraction of the heart, substantiate a rythmic, consentaneous movement of the arteries (§ 384). We carry this with the other facts to pathological conditions. Thus, when the extreme capillaries of the skin, as of the finger, for instance, or any other part, are irritated mechanically, or by any chemical or other agent, an inflammation may be excited at the point irritated; just as the heart, or intestine, is roused into action by the prick of a pin. The inflammation then extends, progressively, from the point irritated, the finger throbs, its principal artery begins to pulsate, and finally the radial. And so of the irritation of the ducts of glands, by which the glandular secretion is increased. Generally, also, remote sympathy, or reflex action of the nervous power, is simultaneously brought into effect.

3. "Hence, all the parts endowed with motion and supplied with nerves from the sympathetic, are, in a certain degree, independent of the brain and spinal cord." This can apply only to the structures of organic life, and as they may enter those of animal life—thus distinguishing the cerebro-spinal from the ganglionic system (§ 215, 233, 475½, 487, 893½).

4. "The central organs of the nervous system can, however, exert an active influence on the sympathetic nerves and their motor power" (§ 222-232, 475).

This is a very important physiological fact to the physician, and is fully established by the experiments of Philip, Valentin, Müller, and others, and is conspicuously shown by the effects of the passions.

It is through the liability of the whole body to be influenced by the nervous power of the brain and spinal cord through the sympathetic nerve, and as generated by the central parts of that nerve that I interpret the whole philosophy of sympathetic diseases, and the operation of all morbific and remedial agents when they affect parts that are distant from the direct seat of their action.—Rights of Authors p. 912.

5. "The experiments of Dr. Philip tend to show that distinct parts of the sympathetic, and the movements dependent upon them,

^{*} Continuous influence of these Institutes (§ 129 e, f, 498 a).

as of the heart, for example, do not derive their nervous influence from distinct regions of the brain and spinal cord; but, on the contrary, that the whole brain and spinal cord, or every part of them, can exert an influence on the motions of the heart," of the capillary bloodvessels, of the intestinal canal, &c. (§ 476-492, 494 d).

6. Next follows a most important physiological law, when applied pathologically and therapeutically, and by which I explain the continued operation of morbific and remedial agents long after the ces-

sation of their direct action.

"The movements excited in organs which are under the influence of the sympathetic nerve, by irritation applied to them or to their nerves, are not transitory and momentary contractions. They are either enduring contractions, or they consist of a long-continued modification of the ordinary rhythmic action of the organ. Hence, in these organs, the reaction consequent on the irritation is entirely of longer duration than the action of the stimulus" (§ 514 g, 516, no. 2, c, 487 e).

Now, what is true of the nervous influence as it respects its effect on the great organs is, according to the experiments of Dr. Philip, and others, equally so of the small blood-vessels, and the vessels of se-

cretion, and as a consequence, of their products.

The foregoing law is founded upon experiments in which the irritation produced by agents is not directly morbific, such as galvanism and mechanical irritants. If such causes, therefore, will continue to derange the actions of the organic viscera after the operation of the causes is withdrawn, those which are truly morbific will continue in action longer, and establish disease more permanently through the same channel. And so of remedial agents. The law is shown, naturally, by the unabated contraction of the sphincter muscles after the evacuation of urine and of fecal matter (See Belladonna &c., p. 674).

This physiological law, therefore, is of vast moment in interpreting the effects of remedial agents, corresponds with that natural condition which is set forth in § 514, g, shows us how the influence of an emetic or cathartic may continue to be felt by the lungs, the brain, &c., long after their most characteristic effects are over; or how an uninterrupted and cumulative action of the foregoing nature may be maintained by small and repeated doses of mercury, antimony, &c., or by the peculiar change which leeches establish in the vessels to which they are applied, and, finally, how a morbific cause of yet other specific virtues may, by its momentary action on the mucous tissue of the stomach, or lungs, &c., be kept up in those tissues long after the remote cause is withdrawn, and progressively shed a morbific influence over all the organs of the body (§ 150, 498 f, 545, 549, 550, 558 a, 559, 666). The impression is maintained, in all the cases, upon the organic constitution of the organs immediately impressed, for an indefinite time after the agents themselves have ceased their operation. While that impression remains the influence which has been thus exerted continues to modify, more or less, the vital nature of the parts, and to be reflected with various effect upon distant organs. have seen the simple physiological elements operating through the combined media of the cerebro-spinal and sympathetic systems, in § 514, f, g, as it respects the permanent contraction of the sphincter muscles, and in the explanation which I have given of the persistonce of their contraction after the expulsion of the urine and fæces.

Now, that principle which physiologists have limited to an explanation of the natural phenomena in relation to the sphincters is most extensively applicable in resolving the problems of disease and of remedial influences, and I shall carry it, in connection with the foregoing law, far into the labyrinth of organic life, as it may fall under the cognizance of the pathologist and therapeutist. In the aspect, alone, of its bearing upon the amount and frequency of doses, &c., in the treatment of disease, the law is of incalculable magnitude (§ 857). The same impressions which are left upon the bladder and rectum after the evacuation of their contents, and which continue to propagate reflex nervous actions to the sphincter muscles, and thus maintain them in a state of contraction till the urine or the fæces again accumulate, equally appertain to morbific and remedial agents. Hence I deduce an important practical rule for the regulation of doses, the frequency of their repetition, the order of their application, &c., according to the nature of disease, the nature of the agents employed, the duration of their effect, &c.; all of which is amply sustained by the results of practice, especially those which so constantly accrue from excessive doses, and their repetition before the influences of the preceding shall have duly abated, or where other means should have been substituted. There is nothing, I say, of greater practical importance in the whole circuit of medicine than what is involved in this section, and in those which I shall have brought to its illustration. We must attend to the physiological facts. The effects of mistaken practice are entirely insufficient to enlighten the understanding. Physiology must be brought back as the basis of pathology, the groundwork of therapeutics; keeping ever before us those natural laws through which the evil and the good of practical medicine are essentially determined. However various the causes and the phenomena, a concurrence of principle and of laws obtains among the whole; which is the surest proof that the doctrines here taught have their deep foundation in nature (§ 237). There is nothing that can assure us more emphatically of the importance of sweeping away the chemical and physical doctrines of life, of disease, of therapeutics, than the facts about which I am now interested, and the mischief which has arisen either from removing pathology and therapeutics from their proper foundation, or in deriving their foundation from the laboratory of the chemist ($\S 5\frac{1}{2} a$, $350\frac{1}{2}$, $350\frac{3}{4}$, 819, &c.).—Note Ff p. 1135.

7. The next following law shows that the organs of organic life are essentially a system by themselves, that their actions are carried on by their own inherent powers, and are essentially independent of the nerves, and that the great office of the sympathetic nerve is to provide a stimulus, and animalize organic compounds. It will be seen, however, that a common error occurs, that "the immediate cause of the involuntary motions lies in the sympathetic nerve" (§ 516, no. 2).

"The immediate cause of the involuntary motions, and the cause of their type, lies neither in the brain nor in the spinal cord, but in the sympathetic nerve itself. Even the influence of the ganglia is not necessary. The branches of the sympathetic going to an organ may be entirely removed, the twigs distributed to the substance of the organ only being left, and the motions will be maintained as before, the reciprocal action between the muscular fibres and these ultimate nervous twigs being apparently adequate to their production."*

^{*} Sec Note Bs p. 1131.

The phenomena are the same in plants. They depend, not on the nervous power, but on the organic properties of every part. This appears from Müller himself, who says that, "to excite the motion of the leaflets and petioles of the mimosa, it is not necessary that either the intumescence, or even the leaves, should be touched. The stimulus may be applied to a more or less distant part" (§ 184, 207, 208, 233, 257, 490, 502, 524, no. 2). Had Müller said the exciting instead of the "immediate cause," there would have been less objection; but the present case is like that in § 264, 498 e, 516 c, 1042.

8. Now follows the great law, that, notwithstanding the foregoing separate nature of the organic properties and their essential independence of the nervous power, the organic properties are constantly influenced through the cerebro-spinal and sympathetic systems. What is said, however, of the "extreme branches of the sympathetic" must be regarded as erroneous (no. 7), though it be certain that influences may be determined by reflex action through the ganglia and plexuses of the sympathetic nerve (§ 459). The law is thus expressed by Müller:

"Although, from the foregoing observations (no. 7), it is certain that the extreme minute branches of the sympathetic have still the power of regulating the movements of the parts not subject to the will (when such parts are abstracted from the body), yet it is not less true that both the brain and spinal cord, and the ganglia themselves, when in a state of irritation, exert an influence on these movements as long as the contractile organs are connected with them through the medium of the nerves. The brain and spinal cord are, however, also to be regarded as the source of the power of the sympathetic itself, which would, without them, become exhausted" (§ 473 c, 524, no. 6).

The last clause of the foregoing law is inapplicable to the fœtus without brain and spinal cord (§ 493 c). As to the exciting cause of motion in the extirpated heart and intestine, the question is important only as it relates to the proof that motion depends essentially upon properties inherent in the tissues, and as involving an implication that the sympathetic nerve embraces in its minute ramifications centres of reflex nervous actions. In its larger branches such centres probably exist (§ 262, 263, 473 c, 498 e, 516, nos. 2, 3, 1042).

The preceding law involves the sum of reflected pervous

The preceding law involves the sum of reflected nervous actions, of the operation of the passions, and of other direct cerebro-spinal influ-

ences on the organic viscera (§ 227, 230).

9. I would vary the phraseology of the following law, to render it more conformable with the facts. I do not believe that the sympathetic nerve is any longer charged with the influence derived from the brain and spinal cord than during its connection with those parts. So far as this nerve manifests an influence after that connection is severed, it is itself the source of that influence; and this conclusion is sustained by the fœtus without brain or spinal cord (§ 1038).

"It results," says Müller, "from the fact already stated (nos. 7 and 8), that the sympathetic nerve is charged, as it were, with nervous power by the brain and spinal cord, which may be regarded as the sources of nervous influence; but that, when once charged, it continues to emit this influence in the manner peculiar to itself, even when the farther supply is, for a time, diminished" (§ 516, nos. 7 and

8; § 520, 524, no. 5).

If the "fact" show anything, it is a certain independence of the

sympathetic of the cerebro-spinal system, which becomes strongly pronounced when the latter is wanting in the fætal state, or when de-

ranged in some chronic maladies.

10. The next law shows that the action of agents is incomparably greater upon the minute terminations of the nerves than upon their trunks. It is equally applicable to the cerebro-spinal as to the sympathetic. Thus:

"The influence of narcotics locally applied to the sympathetic nerve, does not extend to the distant organs which the nerve supplies; but these organs may be paralyzed by the direct narcotization

of the minute nervous fibrils which are distributed to them."

The principle is general, extending to all other agents, and has been misapplied by Müller, and many others, to sustain the humoral pathology (§ 826, d. Med. and Phys. Comm., vol. i., p. 563, 564).

11. The next following law will be seen to be important in interpreting some of the various phenomena of sympathy, when they orig-

inate in the sympathetic nerve. Thus:

"The laws of reflection (in the cerebro-spinal system) stated in the third chapter of this section prevail, likewise, in the actions of the sympathetic nerve. Strong impressions on parts supplied by the sympathetic nerve may be propagated to the spinal cord [and brain], and give rise to motions of parts which derive their nerves from the cerebro-spinal system."

As an illustration of this law, "Volkmann has observed convulsions of the body produced by irritating the intestines of a decapitated

frog."

With the head on, and in animals more susceptible than frogs, the foregoing law becomes extensively applicable to agents applied to the intestinal canal, or other viscera that are especially supplied by the sympathetic nerve. Thus, nux vomica produces spasmodic action of the voluntary muscles, while opium, &c., relieves them in the same way. Indeed, it is well ascertained that all the spasmodic movements of the voluntary and respiratory muscles that arise from affections of the abdominal organs depend upon irritations transmitted to the brain and spinal cord, and their subsequent reflection upon cerebro-spinal nerves. Hence, also, the action of the abdominal muscles in the vomiting excited by irritation of the intestines, by irritation of the kidneys, of the uterus, &c. And so of the natural movements of the respiratory muscles (§ 500, 889 g, 891½ g, k, 903 a, 902 g).

12. "Impressions on parts of which the nerves are derived from the sympathetic are communicated to the spinal cord and brain, and excite the motor influence of the sympathetic nerve by reflection."

The foregoing law is an extension of no. 4, and is the most important of well-ascertained laws in medicine, as explaining all the sympathetic influences of disease, all the influences of remedial and morbific agents exerted upon parts distant from the seat of their direct action; except such phenomena as may also fall more or less under the laws 11 and 13, in connection with which this law should be considered.—(Med. and Phys. Comm., vol. i., p. 569-572.)*

13. "Reflected action of the sympathetic, from an impression communicated to the spinal cord by cerebro-spinal nerves, is a frequent

occurrence" (§ 893 a, c).

The "frequency of the occurrence" is such, that it is through the
* See Rights of Authors, p. 912.

foregoing law, and the 12th, that remedial agents operate upon the organic system when applied to the skin, that diseases of the skin affect the abdominal viscera, that the contact of cold air suddenly increases the excretion, or the discharge, of urine, &c. The 12th law is involved, since both the cerebro-spinal and sympathetic nerves of the skin are the media of transmitted impressions. The chain of involved influences is of the highest importance, pathologically and therapeutically. As one of a thousand illustrations, if tobacco applied to the skin produce vomiting the effect is first propagated to the nervous centres, from which it is reflected upon the stomach through the motor fibres of the par vagum and sympathetic nerve. This irritation of the stomach is equivalent to a direct impression from tobacco upon its mucous tissue (\$503). It is then returned to the nervous centres through the sensitive fibres of the par vagum and sympathetic nerve, and reflected upon the respiratory muscles through the motor nerves of those organs (§ 113, 224, 226, $475\frac{1}{2}$, 500 k, 893, 893 $\frac{1}{2}$).

But there are other profound influences, and other circles of sympathy simultaneously established. The organic properties of the stomach are affected, reflex nervous actions are reverberated upon the skin, displayed in the heart and blood-vessels, in the liver, and other important organic viscera, while these influences also mutually react upon the several organs, respectively, and involve other parts, such as the uterus, the kidneys, the bladder, the voluntary muscles, the sphincters, the senses, the mind, &c., in the deep complexity of results. And all this astonishing consecutive series of effects, moving forward under the most precise and fundamental laws of nature, and all the work of a moment, is set in motion by the simple application

of a leaf of tobacco to the sole of the foot (§ 502, 902 g).

517. Finally, the nervous power may be determined upon the organic properties of the brain, or of any part of the nervous system, by physical and mental causes, with much of the variety of effect which it produces on other parts (§ 230, 512, 1040).—Note Q p. 1122.

518, a. "In certain organs, which are subject to the influence of the sympathetic and of the cerebro-spinal nerves at the same time, a voluntary influence seems to be exerted only after the long continu-

ance of a centripetal or sensitive impression."

So far as this principle is operative, it goes to demonstrate the remarkable peculiarities, the versatile and complex nature, of the functions of the nervous system (§ 500, j and k). The urinary bladder, for example, which is under the influence of the will, presents the following phenomenon: "The will does not come into operation until a considerable accumulation of urine has taken place; in other words, not until the fluid has made a long-continued impression on the sensitive nerves of the bladder, and through the medium of these upon the cerebro-spinal axis" (§ 500, e).

518, b. Analogies evidently occur in the viscera over which the will has no control, while the facts are illustrated by the principle as ascer tained in the foregoing manner; such, for example, as the long incubation of miasmata, of the hydrophobic virus, mercurial influences, &c., and the sudden accession of the phenomena to which they respectively give rise (§ 500 e, 514 g, 516, no. 6). In sections 500, j and k, are some remarkable facts which will deter us from rejecting difficult

problems in sympathy (§ 473, no. 6, 523, nos. 6 and 7).

519. The following law is a farther exemplification of the foregoing comments (§ 518, b), and should be considered in connection with

the 11th and 12th laws. Thus:

"Many parts which are supplied by the sympathetic nerve, and capable of involuntary motion only, become associated with the motions of parts subject to volition; a part of the voluntary motor influence being communicated involuntarily to them; just as in the associate motions of the voluntary muscles."

Of this, examples are afforded by the iris, the vesicula seminalis, and intestine (§ 500, e). It is in this way the will affects the iris.

520. The problem is propounded by Müller, "Can reflex phenomena be produced in the sympathetic nerve through the influence of the

ganglia, and independently of the brain and spinal cord?"

He is disposed to answer the question negatively, and observes that, "We are at present entirely ignorant as to whether irritations in one organ ever, through the medium of the sympathetic, give rise to sympathetic movements in another." And yet when he comes to reason from the phenomena of nature, he remarks that, "in many cases, it is probable that the reflections are produced through the medium of the sympathetic alone;" and again, that in such cases, "it is probable that the sympathetic nerve alone is engaged in the production of the phenomena." This is enforced by the considerations, that, "the peculiarity of the organic or sympathetic nerves, namely, the difficulty of distinguishing either origin or termination of them, their want of (definite) arrangement into trunks and branches, and the increase in their course which they frequently undergo, is certainly in favor of their actions being propagated in all directions from the central points of the ganglia."

This was the old doctrine, which concerned itself mostly about the sympathetic nerve, and the fact is distinctly evinced by many of the phenomena of contiguous sympathy (§ 497), and by the feetus without brain and spinal cord. It seems, also, to have been shown by the experiments of Henlè, Grangier, and Valentin, upon the intestines. But careful attention is necessary, in these cases, to distinguish what is due alone to the independent organic properties of any part, from that which is owing to an influence exerted upon those properties by the nervous power (§ 222, &c., 507, 516, nos. 7 and 8, 1038). In the former case other stimuli operate (§ 490, 498 c).

521. "It is not proved, and several facts have been observed which are opposed to the belief, that the ganglia can exert an insulating action so as to impede the transmission of motor influence from

the brain and spinal cord" (§ 523, no. 4).

All the phenomena of sympathy in organic life appear to be oppo-

sed to this belief.

522. "It is not certain that the ganglia are the cause of the parts supplied by the sympathetic nerve being withdrawn from the influence of the will."

It is probable that the cause is inscrutable, since it is owing to peculiarities in the vital as well as mechanical constitution of the two systems of nerves. We see, however, that influences are as readily transmitted from the brain to the organic viscera as the will operates on the voluntary muscles; and while the passions scarcely operate in animal life, they have a powerful and rapid effect on organic.

Laws of the Sensitive Functions of the Sympathetic Nerve.

523. 1. "The sensations in parts, the nerves of which belong to the sympathetic system, are faint, indistinct, and undefined; distinct and defined sensations being excited in them only by violent causes of irritation" (\S 201, b).

2. "The sensitive impressions received by the sympathetic nerve, although conveyed to the cerebro-spinal axis, may not be perceived

by the sensorium" (§ $199\frac{1}{2}$, 451).

3. "The impressions which give rise to reflex motions, when conveyed to the spinal cord by the sympathetic nerve, are, in most instances, not productive of sensations; while those impressions which are received by cerebro-spinal nerves always give rise to sensations" in natural states. The reflex is our sympathetic sensation (§ 201, 451).

4. "The ganglia of the sympathetic nerve do not prevent the transmission of centripetal actions in that nerve to the spinal cord. They have not an insulating power over its centripetal currents"

(§ 521, 1038).

5. "The ganglia are likewise not the cause of the impressions on

the sympathetic nerve being unattended with true sensation."

6. "In many cases, irritation of a violent nature in organs supplied by the sympathetic nerve gives rise to sensations in those parts. In other cases, the irritation being less violent, the sensations in the parts affected are indistinct, while distinct sensations are present in other parts supplied with cerebro-spinal nerves" (§ 518, b).

We have examples of the first kind in inflammations of the intestines and liver; of those of the second kind, in the troublesome itching of the nose and anus in affections of the intestinal canal, and pain of the shoulder in hepatic and cardiac diseases, of itching of the glans penis in chronic affections of the bladder and kidneys.

7. "The secondary sensations in cerebro-spinal nerves, consequent on irritation of the branches of the sympathetic, occur especially at

the extreme parts of the organs affected."

Morbid states of the stomach produce a sense of irritation in the throat; and nothing is more common than obstinate inflammation of the mucous tissue of the fauces from gastric derangements, which are not inflammatory.* In all these cases, remote and continuous sympathy are more or less in combined operation. An ignorance of the laws which govern in such instances leads many physicians to apply their remedies to the parts where the sensation is felt, or the inflammation appears. There is also a special sympathy between the extremities of the intestinal mucous membrane. Smoking, for instance, often brings on an attack of the piles; though an intermediate chain of morbific influences is also propagated to the anus through the stomach and liver (§ 498 f, 514 ħ, 689 l).

Laws of the Organic Functions of the Sympathetic Nerve.

524, a. 1. "When, in consequence of impressions on sensitive nerves, secretions take place in distant parts, the brain and spinal cord are probably the medium of communication." Thus, "impressions on internal mucous membranes, as by hot drinks, frequently give rise immediately to a general sweat."

* Diphtheria and Fothergill's Sove-throat are merely sympathetic results of profound, insidious, venous congestion of the abdominal organs (§ 689 l).—Note KK p. 1140.

This is precisely similar to what I have said of the effect of food in

lighting up a warmth in a cold skin (§ 512).

The foregoing law is true, in a general sense (§ 455, 458, 459, 490 493 b, 516, nos. 7 and 8). It lies at the foundation of the whole doctrine which I have projected of alterative reflex action, through which I interpret all diseases that spring up as consequences of each other, and the operation of morbific and remedial agents upon parts remote from the seat of their direct influence. It is variously expressed in the preceding laws.

If hot water operate upon the stomach and transmit its influence through the cerebro-spinal and sympathetic system to the whole surface of the body, it is clearly in the same way that tartarized antimony produces a sweat over the whole cutaneous organ when it determines nausea, or the act of vomiting, and therefore, also, when it acts upon the stomach in a more insensible manner. And so of the remote influences of other remedies, or of morbific agents, or of gastric, or any other primary disease. If it be the principle as laid down physiologically, it must be equally the same for analogous effects in disease, or in its treatment.—See Rights of Authors, p. 913.

2. "There prevails a consent of action between the different parts of a secreting membrane. Thus, the state of one spot influences the condition of the whole extent of a mucous membrane" (§ 498 f, 516,

nos. 2, 3, and 7).

This is the *continuous* sympathy as expounded in this work. It is more or less manifested in most of the diseases of all tissues, and although not a function of the sympathetic nerve, I have retained the law under that denomination (§ 141, 498, 520, 923).

3. "A particular state of one organ, such as inflammation, or a secreting action in it, often causes the production of a similar state in

other parts."

This proposition is intended in a specific, not in the general sense in which disease of one part gives rise, by reflex action, to diverse affections of other parts. It refers to peculiar states of disease in which remote sympathy is often remarkably characterized. Thus, "inflammation of the testicle may be replaced by inflammation of the parotid; erysipelatous inflammation of the skin may be transferred to the membranes of the brain; suppression of the secretion of one organ may give rise to increased secretion in another." So of the extension of rheumatism and gout from one part to another of very different organization (§ 142, 893 n, 905 a).

524, b. Where sympathies of the foregoing nature arise, there is often a special relation of natural functions between the respective parts, as between the uterus and mammæ. Or such relation appears to be pronounced only by morbid states, as between the parotid and

testis, and the parotid and mammæ, in the mumps (§ 142).

524, c. As resulting from the foregoing (no. 3), though apparently the reverse of it, we have the important reflex influences, that when disease springs up in distant parts as a consequence of some affection of other parts, the secondary affection often proves curative of the primary one. It is the same, in principle, as when blisters, setons, &c., relieve some internal malady. Many sympathetic diseases have, as it were, a great final cause, as a part of the natural constitution of animals. The ordinary forms of inflammation which supervene on

venous congestion often relieve a more formidable affection of the veins (§ 803, 804, 905. Also, Med. and Phys. Comm., vol. ii., p. 519-524). Inflammation of the bronchial mucous membrane, or of the pleura, supervening on pneumonia, may assuage the latter affection. Phthisis, supervening on gastric disease, sometimes removes the latter condition. Eruptions of the skin relieve disease of the internal viscera. The hepatic action which leads to morbid redundances of bile mitigates cerebral or other congestions and inflammations, and the effusion relieves the liver; while it is the tendency of inflammat on of all parts to relieve itself by some morbid product, whether the disease be primary or secondary. Nature, in these cases, has supplied indications for the hand of art; and, instead of waiting for the indirect and spontaneous course, we should abstract blood, or hasten to establish those changes which result in increased secretions, &c. While, also, we are accomplishing these results, which, abstractedly considered, are depletive, we are acting, at the same time, upon the diseased properties, either by a direct impression upon them by the remedies, or indirectly by reflex nervous action (\$ 503). But this is mainly true of the natural processes as it respects spontaneous hemorrhage. All the other natural effusions are greatly wanting in those direct remedial effects which are exerted by therapeutical agents that lead to similar products.

"The principle of the balance of sympathy teaches us how we must avoid aggravating the morbid condition of one organ by the means which we apply to another; but it also teaches us how we may produce a change in the state of one organ directly inaccessible to us by effecting an appropriate change in another."—MÜLLER. Here Müller is any thing but a humoralist, as, also, throughout his disquisition on the laws of sympathy; though in other places he lays down the broad doctrine that morbific and remedial agents produce their effects by absorption into the circulation (§ 494 dd, 514½ b. Also, Med. and

Phys. Comm., vol. i., p. 563-571).

524, d. It might seem, at first glance, that the fact of the vital properties and actions being liable to disease is inconsistent with the great laws of recuperation and self-preservation. But it is not so; since morbific agents being permitted, their occasional deleterious action grows out of the natural constitution of the properties of life, which is physiologically designed for the healthy processes. That these processes may be carried on, the properties of life must be susceptible of being acted upon by foreign agents, as food, &c., and universally by the blood. They must also be liable to modifications in their nature, that certain specific functions may be instituted from time to time, as the processes of gestation, lactation, &c., and the powers of all other parts must be so constituted as to adapt themselves to these transient modifications. And so of other changes, as from infancy to childhood, from childhood to puberty, &c. (§ 153-159). Now the changes which arise in disease are analogous to those of gestation, lactation, and more remotely to those which occur at puberty; and they are, therefore, necessary consequences of the natural and essential constitution of the vital properties when noxious agents act upon them. We therefore return again to our proposition that it is even a necessary consequence of the final cause of the adaptation of the properties of life to the influence of salutary agents. And hence, also, the natural law of adaptation (§ 136) extends to morbid states of the system, being, for example, the principle already adverted to, which protects the general system against those morbid changes in the blood that ensue upon local diseases, and diseased parts against the irritation of their morbid products (§ 74, 129, 137 c, 143 c, 150-152, 155, 156, 387, 524 c, 944 c, 980, 1019, 847-850).

4. "The ganglia appear to be the central parts from which the

vegetative influence is distributed to the different organs."

5. "This radiating influence appears to be, in a certain degree, in-

dependent of the brain and spinal cord" (§ 520, 516, no. 9).

6. "It appears, however, that the brain and spinal cord are the main source whence the power of the organic nerves is gradually ren

ovated" (§ 1038).

7. The sympathetic nerve modifies organic functions and their products, and supplies the stimulus of the nervous power to muscular fibre in organic life (§ 224, 455 a). Every organ, through this channel, is rendered sensitive to the condition of each other, and they so interchange their influences upon each, that the whole are maintained in those relative states of action which are most conducive to the good of the whole. From the exquisite susceptibility of the nervous power, and of sympathetic sensibility, which is so conspicuous in this function, arise those disturbances that are inflicted by organs upon each other, and the reflected influences of remedial and morbific agents (§ 113, 224, 455, 461, $461\frac{1}{2}$, $475\frac{1}{2}$, 487h, 500g, 516d, nos. 7-9, $647\frac{1}{2}$, 893, $893\frac{1}{2}$).

SYMPATHIES OF THE INDIVIDUAL TISSUES-REFLEX AND CONTINUOUS.

Sympathies of Similar Tissues.

525, a. Enough, perhaps, has been said upon this subject (§ 85–117, 133–143). We have seen that tissues of a similar vital constitution have the greatest tendency to sympathize with each other; but it is not necessary that the secondary disease should be of the same nature as the primary, though such is apt to be the case (§ 140, 141, 149–152).

The most frequent instances of morbid sympathies in tissues of the same nature, but remote from each other, occur in the following or-

der (§ 162):

1. The venous tissue, in the form of venous congestion (§ 786, &c.).

2. The fibrous tissue, as in rheumatic inflammation.

3. The serous tissue, as seen, especially, in dropsical affections.

4. The mucous tissue.

- 5. The cellular tissue.
- 6. The lymphatic tissue.
- 7. The nervous tissue.
- 8. The arterial tissue.
- 9. The muscular tissue.
- 10. The osseous and cartilaginous tissues.

525, b. When similar tissues sympathize with each other, the sympathetic disease and its phenomena are apt to be similar to the primary affection; while, in the case of sympathics arising among different tissues, the phenomena are different in each, even though the primary and secondary affections be of the same general nature, as,

however, they are not wont to be. When like tissues sympathize with each other, the diseases and the phenomena are most analogous because the same tissue in different compound organs has, respectively, modifications of the organic properties that are more alike than those of different tissues. And hence, mainly, the greater difference between the primary and secondary diseases of different tissues (§

133-140).

525, c. When disease springs up in tissues of the same organization, but remote from each other, as in rheumatic inflammation of the fibrous tissues, for example, the primary affection often exists in some other part or parts, as the digestive organs, and is generally of a different character from the secondary affection. In these cases, which are common, the successive secondary affections may be more owing to reflex influences of the parts primarily diseased than to the sympathetic influence of the tissue secondarily affected upon other parts of its own denomination. This is an important practical consideration, for upon its just estimate will depend much of the treatment in any given case of disease (§ 902 m, 905). It is also equally true that the sympathetic affections which supervene among compound organs are apt to be more or less different from the primary affection.

526, a. Tissues morbidly affected sympathize, continuously, in their several parts, most readily in the following order (§ 133–136, 498):

- 1. The venous tissue, in congestion or sub-inflammation.
- The lymphatic tissue.
 The cellular tissue.
- 4. The mucous tissue.
- 5. The fibrous tissue.
- 6. The serous tissue.
- 7. The glandular tissue.
- 8. The dermoid tissue.
- 9. The nervous tissue.
 10. The muscular tissue.
- 11. The cartilaginous and osseous tissues.
- 12. The arterial tissue.

Owing to the peculiar vital constitution of each tissue, disease is apt to be confined to that which it first invades, but to disturb the condition of other parts with which it may be associated (§ 133-136). There are, indeed, some striking exceptions to the general rule; as, rheumatic inflammation of the ligaments is often propagated to the heart, and sometimes to a mucous tissue. Inflammation of the pulmonary air-cells is very apt to be extended to the serous tissue of the lungs, or inflammation of the liver to its investing membrane. Indeed, the serous membranes generally participate in the morbid states of the other tissues with which they are associated; nor can much intensity of disease affect any tissue without disturbing, more or less, the condition of its associate tissues. But there is much variety in these respects, even in continuous organs, as between the stomach and the small and large intestines. If the mucous coat of the small intestine be actively inflamed, it is frequently the cause of a like condition in the peritoneal coat, when the mucous inflammation may subside as a sympathetic consequence; thus representing the double operation of the law in § 524, no. 3. But, however severely the mucous coat of the stomach may be affected with inflammation, the disease is rarely propagated to the serous tissue of the organ, but far more readily to the serous or other tissues of the lungs, &c.

In respect to the arterial tissue, when we regard the extreme and capillary series as the instruments of all diseases, and, therefore, always involved in morbid action in the diseased states of all other tissues, it must rank as the first in its liability to continuous and remote

sympathetic influences (§ 1040).

The arterial tissue itself is but little subject to other conditions of morbid action; and when the large arteries become inflamed in any part, the disease remains very circumscribed. They have, also, no great action in their natural state; it being their office, mainly, to serve as conduits for the blood. Nevertheless, they are constantly liable to sympathetic irritations, either by continuous influence or reflected nervous action. The next series, or the capillary arteries, are reservoirs of blood to the extreme vessels; and to meet the exigencies of this function, they have their vital properties and actions more strongly pronounced, and are readily and manifestly influenced by the nervous power, as abundantly shown in blushing, &c. (§ 512, b). Hence, from this natural, physiological constitution, this series of the arterial system is more liable than the larger to irritations and augmented actions, as manifested in most inflammations (§ 715–719).

We come next to the extreme series, in which the capillary arteries terminate; and here we find the vital properties developed in an eminent degree. This is known from their being the essential instruments of all healthy and morbid processes; and the changes in their phenomena and products during disease evince the rapidity and great extent in which these properties and actions may be modified by the nervous power, and which are brought about in an instant of time when that power is developed by the mind (§ 227, 500, 516 d). Reflex nervous action plays an incessant and extensive round among this extreme series of vessels, both in health and disease. A breath of cold air may arrest the secretion of sweat, and simultaneously determine an increased flow of urine, or fear will as suddenly augment both excretions. Coming to disease, and the influence of remedial agents, this natural relationship of the extreme vessels, and the same physiological principle, are at the foundation of the principal philosophy. Indeed, the organic properties being now more susceptible than in health, and the nervous power more intensely developed by morbific and remedial agents, its operation must be more rapid, extensive, and profound, in the latter than the former case. Hence, in part, inflammations, &c., are liable to spring up in rapid succession in various remote organs, after their invasion of any one part (§ 1056).

526, b. Next, as to the venous tissue. Here the sympathies are great, both of the remote and continuous kind, particularly the latter (§ 498). It is especially through the natural physiological sympathies of the veins, that I have endeavored to show how they co-operate in circulating the blood, as also the error of the physical doctrine of venous congestion, which supposed that this most prevalent and fatal disease depends on obstacles to the circulation and consequent stagnation of the blood. I have, therefore, endeavored to expound the pathology of this affection upon purely vital grounds, and in conformity with physiological laws (§ 786, &c.). The main physiological prin-

ciple of a sympathetic nature, however, should be stated in connection with the subject before us. The venous radicles possess a vigorous action which is constantly influenced, through continuous sympathy, by the corresponding state of the capillary arteries, and by the quantities of blood transmitted to them; and that the trunks of the veins have a most visible action is shown by their rapid contraction and dilatation when cold or heat may operate upon the skin. This action is simultaneous, or nearly so, over a large extent of the veins, and is the result of continuous sympathy with the arterial system, as well as dependent on the quantities of blood transmitted and upon reflex nervous action. But, when an increased quantity is transmitted, the enlargement of the veins is in no respect mechanical, but produced, in part, by the greater impression which is thus made upon the exquisite susceptibility of the organic properties of the veins.

From these few remarks as to the vital endowments of the veins, and of the active functions they perform, it is evident that they must be quite liable to morbific influences, and that remote and continuous sympathy of a morbid nature must have a ready operation among

them (§ 74, 117, 137, 155, 156, 387, 422, 514 h, 524 d).

526, c. In respect to the lymphatic system, the principle of continuous sympathy, as in the veins, is strongly exhibited under the influence of irritating agents. If a lymphatic become inflamed at some point in the skin, the inflammation may extend rapidly along the course of the vessel, while the glands, also, will take on the same condition. Here is the great bulwark of humoralism. Here it is, and in the lacteals, that the humoral pathologists suppose that morbific agents enter the circulation and corrupt the blood, or remedial ones are equally absorbed, and transmute it from a morbid to a healthy state! But, since the needle, whose prick may propagate an extensive inflammation along the course of a lymphatic vessel, is not absorbed, nor the leeches which remove the inflammation, we may rest satisfied that the poison of the viper, of the mad dog, &c., do not produce their effects upon the principle of absorption (§ 268, &c. Also, Med. and Phys. Comm., vol. i., p. 480-514).—Also § 494 a-e, 514 g, 828-829.

Diseases of the lymphatic glands are especially owing to constitutional predispositions, as in scrofula. When disease is developed in any one or more of these glands, others readily take on the same state of inflammation. While, therefore, under special circumstances, remote sympathy predominates in the lymphatic glands, the continuous

form is mostly witnessed in the lymphatic vessels.

In the great plan of organic Design, those inlets of the absorbent system, the lacteals, are greatly exempt from morbific influences.

526, d. Sympathies between the brain, spinal cord, and nerves, and between the nerves themselves, are more or less in progress, in the natural state of the body. Their phenomena, however, are not very manifest, unless the nerves of some particular part sustain an irritation (§ 501). Thus, the irritation from stone in the bladder occasions morbid sensations in the penis. Other examples occur in § 523, no. 6. When disease is produced, sympathetically, in the brain, or spinal cord, or nerves, by morbid states of other organs, it is not due, as supposed by Müller, to sympathy with the nerves of the parts so affected, but to the morbid change in the general vital constitution of such parts. In this respect, the sympathies of the nervous system with other or-

gans observe the same laws as apply to other sympathizing parts both as to disease and its resulting reflex nervous actions (§ 230).

It is difficult to analyze the sympathies which occur, specifically, in the nervous tissue, since it is the medium through which remote sympathies take place. Continuous sympathy we know to be of very limited extent, and have every reason to believe that the great final cause of the nervous system is protected by an unusual exemption of this system, especially such parts as supply the organic viscera, from severe morbid conditions, which never fail to inflict great injuries upon other parts. It is also true that diseased conditions of the nervous tissue are not easily reached by remedial agents; and the injury they inflict on other parts constantly reacts in maintaining morbid states of the nervous tissue.

The sympathies of which I am speaking refer to the changes which may be produced in the organic state of the nervous system, not to the transmission of impressions, nor to the development and influences of the nervous power, excepting so far as this power may be productive of direct changes in the organic properties and actions of the nervous tissue (§ 230). The general convulsions that arise from irritation of the nervous expanse in the intestinal canal, or from teething, &c., imply no absolute disease of any part of the nervous system; but only a strong development of the nervous power, and its forcible reflex action upon the muscles that may be spasmodically affected (§ 223–226, 233, 500, 891½ b, g, k, 893½, 903, 984 b).—Note Q p. 1122.

I therefore think that authors, as Marshall Hall, for example, in his work on the Nervous System, are wrong in considering "all convulsive affections to be diseases of the true spinal or excito-motory system." On the contrary, I apprehend that in most of these cases there is no actual disease of any part of the nervous system; and it is of no little practical importance that this question should be rightly settled. The "principal causes," says Dr. Hall, "are dental irritation acting through the fifth nerve; gastric irritation acting through the pneumogastric; and intestinal irritation acting through the spinal nerves."

Now, we have variously seen how the nervous power may be preternaturally excited, and determined with various effect upon the organs of organic and animal life; being so constituted as to be exquisitely susceptible to a vast variety of natural causes (§ 226, 227, 500). The muscles of animal life are naturally under the powerful influence of the nerves; this being a special ordination in relation to the nervous power and the mobility of muscles of animal life, to enable the will to determine the nervous power so as to produce voluntary motion, and other causes to render it subservient to respiration (§ 205, 208, 226, 233, 500 c). Hence convulsions readily spring up; while, from the nervous system being designed for vital objects in organic life, preternatural influences of the nervous power give rise to other phenomena in that division of life. Owing, also, to these constitutional peculiarities, as well as to the natural modifications of the vital properties of the animal muscles, the nervous power, when determined with violence upon them, rarely occasions disease; while in respect to the same properties in the organic system, where they have a different modification, and the nervous power a different physiological function, it readily proves morbific (§ 133-150, 452-456, 8932).

We have, therefore, all the elements that are necessary to show that

Dr. Hall's pathology is wrong. The convulsions to which he refers as actual diseases of the spinal system affect the muscles of animal life, upon which the will may operate with violence in an instant, or which are perpetually held in action by the nervous power for the performance of the respiratory movements, and to carry out the office of the sphincters. A slight irritation, therefore, propagated to the nervous centres may rouse these natural motions into irregular and more violent ones, without producing any more disease in the nerves or the muscles than is produced by the operation of the will, or by those causes which maintain the movements of respiration. Again, if a cere bro-spinal nerve be irritated, convulsions are produced, and the same is done by a shock of the electric fluid. Now, these results are exactly analogous to the natural convulsions which are supposed to depend on "disease of the true spinal system of nerves." If we analyze the supposed cases, the same conclusions will follow. When, in one case, the gum is lanced down upon the tooth, the convulsions may cease immediately. In another, or when the convulsions depend on gastric or intestinal irritation, a dose of morphia, or an emetic, or an enema, or warm bath, will generally remove the convulsions very speedily, and they are not apt to return (δ 893½).

Diseases of the membranes of the brain or spinal cord, or of the substance of the brain or of the spinal cord itself, do not often occasion convulsions; which, indeed, are commonly independent of any disease of the nervous system. When, however, they do give rise to convulsive movements, or when such result follows an affection of a nerve, as in traumatic tetanus, there is no morbid state sympathetically induced in any other part of the nervous system, but the convulsions are owing to a propagation of the nervous power upon the muscles as in the foregoing cases. Here, the disease of the nervous tissue is exactly equivalent, in developing the nervous power, to the irritation propagated to the nervous centres by dentition, intestinal irritation, &c. It sometimes happens, therefore, that a division of the

affected nerve, in tetanus, will at once remove the spasms.

When, therefore, convulsions arise from dentition, or intestinal irritation, we apply our remedies to the gums, &c., and not to the spinal cord, or to its nerves. Such as may depend upon disease of the nervous centres, or of a nerve, are obstinate, and the treatment is then directed with a special reference to the part which may be thus affected. Here the nerve-action is direct, there reflex (§ 227, 500 c, d).

Here, also, we learn the importance of an intimate acquaintance with the laws of the nervous power, and of correct theory. Convulsive movements, under most circumstances, have a very similar character; and to ascertain their causes, we must apply ourselves to other symptoms and other considerations. Nevertheless, they are apt to have certain differences in some affections. Those of tetanus have the strongest peculiarities; and here there is a very limited state of disease at the wounded part, but idiopathic tetanus may depend upon intestinal disease. But, there is often a complete resemblance between the ordinary convulsions from dentition, and gastric, and intestinal irritation, and those of hysteria and epilepsy; whatever may be the exciting causes in either case. Since, therefore, it may be of the highest importance to ascertain the particular causes, we institute a diagnosis through other attending facts (§ 893½).

Sympathies of Dissimilar Tissues.

527, a. Morbific reflex nervous actions occur less frequently among organs of different organization than among many of those which are constituted alike, with the exception of the mucous tissue of the alimentary canal and other parts, and between the skin and other parts. Between these two organs and all others there is, on the part of the latter, the most intimate connection by reflex nervous actions, especially the mucous tissue of the stomach (§ 512); and it is through this natural relation, and the increased susceptibility of diseased parts, that remedial agents so readily exert their effects upon the diseases of all organs, when such agents are applied to the intestinal canal or to the skin (§ 113, 465, 516 d, nos. 12, 13, 889 g, 891 $\frac{1}{2}$ g, k, 892 g, h, 893 a, c).

527, b. Morbific reflex nervous actions between the alimentary canal and other tissues are variously considered in the progress of this work. Those between the skin and other tissues deserve farther consideration in this place. Their predominance and intensity between that organ and the alimentary mucous tissue are shown in the dependence of a vast proportion of cutaneous eruptions upon primary disease of the latter tissue. There is great reason to believe that such is the fact even in relation to measles, scarlet fever, and small-pox, when it occurs spontaneously, and probably also in the inoculated form; though, in the last case, there must be first a reflected influence from the artificial pustule of the skin upon the intestinal mucous membrane, from whence the influence is propagated back to the whole surface of the body (§ 902, m). This construction, so opposed to the humoral pathology, is sustained by the analogy which is supplied by most other cutaneous affections, and by the direct fact that the eruption of scarlatina and of measles appears in the mucous membrane of the throat before it does upon the skin. The eruption, especially of measles, is apt to be preceded, also, by inflammation of the mucous tissue of the eye, the nose, and lungs, as well as by cough. But, as will have been seen, it is not necessary that the secondary, or sympathetic, disease should be like the primary; especially in parts that are dissimilar (§ 527, d). If this pathology as to the consecutive order of developments be true, it is of great practical importance; since it assures us that great care must be bestowed upon the intestinal mucous membrane, as a principal seat of the radiating morbific influences. But the severity of small-pox, &c., depends greatly upon the extent of the cutaneous affection, and its consequent reaction upon the abdominal organs (p. 347, § 516 d, no. 13); and hence the advantage of moderating the eruptions by local applications. Can humoralism explain? Why such definite periods of rise and decline (§ 654 b)?

Sympathies between the skin and kidneys are naturally instituted for special exigencies of the animal economy; but these organs are so constituted in their relative susceptibilities, that the great final cause of their physiological relations shall not be defeated by the propagation of morbific reflex nervous influences from one to the other (§ 422, &c.).

Sympathies between the mucous and serous tissues are comparatively rare in health, and, therefore, in disease. Since, also, the same principles, in a general sense, are concerned in the remote influences of remedial agents, we thus understand why medicine taken inwardly has so moderate an effect upon peritonitis, or pleuritis, &c.; and this

philosophy is clearly confirmed by the ready action of cold upon the skin in developing inflammation of the pleura, and by the manner in which that inflammation may be often overcome by blisters or other irritants applied to the skin. Indeed, so extensive are the natural sympathetic relations of the skin to most internal parts that there is scarcely an inflammation of an internal tissue or organ that may not be more or less mitigated by irritants applied over the neighboring surface, if the application be not prematurely made (§ 514 d, 893 a, c).

There is a very intimate sympathy between the fibrous membranes and the cartilaginous and osseous tissues, which leads to the determination of morbific reflex nervous influences among them (§ 141, b).

527, c. Sympathies of different tissues with each other, of much intensity, are more common in parts that are distant than among the

tissues of one and the same compound organ.

527, d. When disorders arise among different tissues, they are, as I have said, apt to be more or less different from the primary affection, or if alike, their phenomena more variable than among tissues of the same organization (§ 525). The primary affections may be mild while the sympathetic are severe. This relative mildness and intensity is constantly seen in the supervention of inflammations and congestions in remote parts as consequences of some minor derangement of the stomach, or other digestive organs, and in the manner in which severe diseases of all parts are subdued by the action of remedial agents upon the stomach. So, again, the action of cold upon the skin induces, by reflex action, inflammation of any of the tissues of the lungs, or of the intestines, uterus, liver, ligaments, &c.; but here no actual disease is produced in the skin, and the morbific agent is also of a negative nature. Hence a difficulty, notwithstanding its importance, of detecting the original source when a complex series of sympathetic affections has ensued (§ 514 d, h, 527, b).

Sympathics of Individual Tissues in their Relation to each other un Compound Organs, and with entire Organs.

528. When any tissue of a compound organ becomes the seat of disease, the influence of such disease is felt, more or less, by all the tissues of such an organ, where the primary disease is at all severe; especially in the organs of organic life. The tissues, as we have seen, which are secondarily affected may or may not sustain the same character of disease as the original affection; and this will depend much upon the nature of the organ. The sympathies, for instance, between the different tissues of the lungs are far greater than between the different tissues of the stomach, and I may say, indeed, of any other organ. If the mucous coat of the stomach be even severely inflamed, the disease generally remains limited to that tissue, and will far sooner give rise to inflammation of the pulmonary mucous membrane than it will be extended to the cellular, muscular, or serous tissue of the stomach, however much it may otherwise disturb their functions. On the contrary, however, it is quite otherwise with the lungs; especially when the cellular or parenchymatous tissue of these organs is actively inflamed, or when chronic disorganizing inflammation invades the same tissue. In either of the cases, the inflammation is apt to be propagated, sooner or later, both to the serous and mucous tissues of the organ (§ 115-117, 129, 132-155). And

here may be observed a wise ordination of Nature for the ultimate relief of so grave a disease as acute or chronic inflammation of the main substance of the lungs; an augmented secretion of mucus or serum contributing to that result, in connection with a reflected sympathetic influence of the action which is necessary to those increased products (§ 74, 117, 129, 137, 155, 156, 387, 422, 524 d, 525). When these redundant secretions take place, the general law is that the primary and secondary inflammations begin to abate. The salutary influence of the secondary disease independently of the depletive effect, is seen in the frequent abatement of chronic muco-inflammation of the lungs or of the stomach when it may supervene in one organ or the other as a sympathetic consequence of a primary inflammation of either, the philosophy of which is fully expounded in § 905 a.

SYMPATHIES OF COMPOUND ORGANS WITH EACH OTHER.

529, a. Compound organs generally sympathize most readily with each other in proportion to the relation of certain functions which they may perform, and the importance of those functions, the stomach always excepted (§ 528). These groups or systems of organs have been already specified, and the sympathies to which they respectively give rise among their component parts sufficiently designated (§ 124–130,

149, 150).

529, b. Morbid sympathies are influenced by a great variety of accidental causes, although they depend essentially upon the constitutional relations of the various parts of the organism to each other. One of the most remarkable is the determination which is given to reflected nervous actions by almost inappreciable impressions exerted by morbific and remedial agents upon some particular part, according to the nature of their virtues, one agent ultimately involving the whole system in morbid action, or one remedy being as extensively curative (§ 149); while others, far more intense and rapid in their operation, are very circumscribed in their analogous sympathetic effects (§ 149, 150, 163). In the case of the morbific agents where many organs are brought into sympathetic derangement, the various results may be mostly due to the action alone of a single cause, as with the miasmata of fever, the virus of small-pox, of scarlatina, &c.; or, the complex results may be greatly owing to the united action of many causes. In the case of remedial agents, their effect as to extent, intensity, &c., will depend much upon the exact nature of the pathological states.

530. Having now arrived at the end of our long journey over the enchanting paths of sympathy, I cannot but hope that they, to whom the mere physiological explorations may be new, will have gained many treasures that will adorn their knowledge, and render medicine a subject of their profound veneration and care. An attentive survey of all the facts will assure them how far they have lived on in ignorance, how much intellectual enjoyment has been lost, how they have been beguiled into the chemical and physical doctrines of life; and, if what I have propounded of the applicability of the natural laws of reflected actions of the nervous system to pathology and therapeutics be founded in truth, the realities of Nature and the substitutes of art will strike with greater force, and supply a never-failing source of advancing knowledge, a shield against the corruptions of ignorance or ambition, a guide to practical habits, and a blessing to

the sick. The natural laws of the nervous system are settled by dem. onstration; as well settled as the laws of gravitation, or any of the most undoubted in physics or chemistry. Such as are immediately applicable to the higher and more difficult branches of medicine I have selected from authors who have had no such objects in contemplation, that they might come unalloyed with the suspicions attendant on theory. My attention, in this respect, has been mostly turned to the great Prussian Physiologist, by far the greatest of the age, and to the invaluable experiments by Wilson Philip. I commend them again and again to all those who would study medicine as founded in Nature, and escape the temptations which have been devised for the gratification of indolence, or for the accommodation of imbecility. We have seen it said, in high quarters, that "the time is approaching when the foundation of practice on the laws of Organic Chemistry will form the distinction between the enlightened physician and the mere pretender" ($\S 5\frac{1}{2} a$, 289–292, 349 d-376 $\frac{3}{4}$, 438–448). I repeat the declaration as expressing the ascendant spirit of the age, and that all who may be disposed to encounter the threatened degradation may duly realize the importance of a firm determination to maintain their ground (§ 440, b).

B. Functions especially relative to the Mental Principle and Instinct.

531. The present subdivision of Peculiar Functions having no special relations to organic life embraces but transient subjects for consideration in this work (§ 450). It comprehends,

1st. Voluntary motion.

2d. Functions by which the mind and instinct act on external objects

3d. Other mental and instinctive functions.

532. The subject of voluntary motion has been already sufficiently examined (§ 215, 227, 232, 256, 257, 486, 487, 500).

533. The functions by which we act on external objects are performed through volition and the voluntary muscles. The philosophy is the same as in § 532.

534, a. The brain co-operates with the mind, and with the instinctive principle, in the acts of intellection or instinctive functions

(§ 241, 500 o, p).

534, b. Although the soul be an immaterial and imperishable substance, it is so associated with the brain that a healthy state of this organ is generally necessary to the ordinary functions of the mind, as

it is, also, to those of instinct.

In a general sense, the mental functions suffer in proportion to the extent and suddenness of cerebral disease; and the same is true of the influences of the brain upon organic life. There is not always, however, a correspondence between injuries and diseases of the brain and the resulting affections of the mental principle. Apparently slight injuries or diseases of the organ will suspend or abolish the faculties of the mind, while in other cases their integrity is preserved under the most appalling affections of the brain. It is also remarkable in those cases where the mind is least affected or unimpaired, that the organic functions are apt to suffer least.—(Med. and Phys Comm., vol. ii., p. 139, note.)

^{**} Subject continued in Appendix, article Soul & Instinct.

VITAL HABIT.

535. VITAL HABIT relates to the modifications of functions, and the variations of their results, in organic and animal life, as arising from the repeated or continued operation of natural, morbific, or remedial agents. It frequently happens, however, that the single application of a vital agent will establish this condition (§ 516 d, no. 6; § 545).

This simple principle is at the foundation of some of the most profound and comprehensive laws in medicine (Rights &c., p. 919, no. 19)

536. The functions of organic beings, plants as well as animals, are liable to great and more or less durable changes from the foregoing causes. I have applied the epithet *vital* to distinguish this constitutional law from those ordinary *physical habits* which are almost peculiar to man, and of which *vital habit* is a common result.

537. The functions of animal life, in man especially, are more under the influence of vital habit than the organic. The latter are variously affected, as to habit, by climate, season, food, and morbific and remedial agents, and by disease. The results of habit are most important in its relation to the groups of causes now mentioned.

538. Habit is liable to be more strongly pronounced in plants and animals by certain influences, particularly domestication, climate, and soil, than in man. Thus, as to vegetables, the ricinus communis is an annual herbaceous plant in America, while in India and Spain it is a woody perennial tree. The acquired power of enduring cold is strikingly manifested in man, animals, and plants (§ 442, 1046–1050).

539, a. The philosophy of vital habit consists either in a tendency of any given condition of the vital states to remain without change, as a consequence of its duration, or in certain impressions or changes that are produced in irritability, sensibility, and mobility, in their relation to each operating cause, by which their susceptibility to the action of the particular cause or causes is diminished or increased (§ 176–215). The philosophy is alike applicable to the properties of the mind as to those of the vital principle, and, of course, to the functions of each (§ 173–176).

539, b. In animal life, therefore, habit concerns the senses, voluntary muscles, and the intellectual and instinctive faculties. In organic life, it refers to the organic properties and functions of every part, whether organic or animal, and takes in the various and important influences of the nervous system (§ 110-117, 224, 226, 495, &c.).

539, c. Since, also, the influence of habit in either life generally relates to the particular agents only by which it is induced, we learn the advantages of interchanging cathartics, anodynes, &c. (§ 149, 163, 550). And so of the different modes of exercise, as it concerns both organic and animal life; and so, too, of the employments of the intellectual faculties, that a due improvement may be imparted to each (§ 565, 566, 855, 872 a).

540. The principle of habit is every where the same; always relative to impressions, more or less durable, upon the vital or mental constitution. The analogy is perfect throughout, in all its details, and is utterly subversive of every chemical or physical view of life or

disease (§ 1047).

541. It illustrates the instability of the vital properties (§ 177-223).

542. The modifications arising from vital habit exercise an important sway in the treatment of disease; since remedial agents must be varied in kind, force, quantity, time of repetition, &c., according to the artificial modifications of irritability and sensibility, especially the

former (§ 150, 188-204, 857).

543. Habit is liable to obtain under the repeated or continued op eration of almost all agents which are capable of affecting the vital or mental properties. Exceptions occur in sensibility as it respects pain from injuries, and in the ordinary pleasures of sense, which are always about the same, however frequently repeated. But the pain on tasting acrids, the nausea from tobacco, &c., may cease to be produced by repetition of the causes. So, also, of the bougie, music, landscapes, the verdure of spring, &c., which are more or less variable in effect. An interval of suspension, however, in these cases, restores the original effect of the causes.

544. It is by vital habit that morbific agents, such as miasmata, cease to be injurious. This is most likely to happen if the individual reside from infancy in the miasmatic region, or, in the unacclimated, after recovery from an attack of the miasmatic disease. Such is the philosophy of acclimation (§ 539, 551); and the same is alike applicable to tobacco, &c., and to its ultimate conversion into a luxury.

545. Sometimes the single application of a particular agent will so confirm the intensity and permanence of habit that it becomes forever afterward inoperative. Such is not unfrequently the case with miasmata, and it is conspicuously shown in small-pox, measles, scarlatina, &c. And so of vaccination in its relation to small-pox; though repetitions of the vaccine disease may be necessary to even a temporary exemption from small-pox, while at other times the effect goes off, feaving individuals exposed to small-pox (§ 350, no. 45, 543). All this shows, too, a near identity between the vaccine and variolous diseases (§ 75-79, 552 a, 654 b).

546. The law of habit applies extensively, also, to remedial agents; these having the effect, by repetition, of lessening or increasing the

susceptibility of organs to their respective virtues.

547. Habit, in respect to remedies, as, also, to morbific causes, demonstrates their reflex nervous influences, and that they do not operate by absorption. Introduce the agents with any frequency into the circulation, there will be no such manifestations of the laws of habit.

548, a. The effects of habit in organic life are generally most permanent when induced by causes of unceasing and long-continued operation, such as climate, the presence or absence of light, &c. There is then some very persisting or permanent modification of the organic properties, and sometimes very remarkably of the structure (§ 74, 538, 545).

548, b. The foregoing law is of very extensive application in the philosophy of disease, and replete with practical bearings. Its illustrations are constantly seen in the obstinacy of chronic diseases, and in the comparative inefficiency of remedies when the treatment of

fevers is neglected for a single day.

548½, a. In a general sense, the natural vital stimuli, such as food which is of easy digestion, heat, water, &c., for obvious final causes, produce, like the blood, nearly the same impressions upon the organic properties, at every age, and at every hour, under equal circumstances (§ 136, 137).—See Causes, Final, Index I.

548½, b. Nevertheless, certain kinds of food, and analogous stimuli, as wine, &c., come within the law of habit. This is where the kind of food may not be natural to the age of the individual (§ 568); or when it may be at first oppressive or detrimental at any age, it may become, by use, inoffensive and nutritious. During the first experiments the food may escape the stomach undigested, having, also, irritated that organ, induced headache, &c. But, in a process of time, the irritability of the stomach becomes adapted, by habit, to the presence of that particular kind of food, its ready digestion follows, and all sympathetic results disappear. It is exactly the same law that renders tobacco, asafætida, &c., luxuries (§ 543).

549. The law of habit, in respect to morbific and remedial agents, follows the law which governs the relative duration of disease when produced by remedial agents and such as are truly morbific. Disease excited by the former, if not in great intensity, soon subsides spontaneously; but when by the latter, it is far more lasting. This principle, also, as it relates to remedial agents, is at the foundation of their

curative effects (§ 893, &c., 926).

550. Since habit subsides in various degrees, and at various times, after the removal of its causes, and the properties of life acquire, therefore, more or less, their original susceptibility to the particular agents or causes (§ 539, 543), and since the effects of remedial agents are commonly transient in respect to habit (§ 549), we may, in most cases, soon resume the suspended remedy, and obtain its original effect (§ 539 c, 857). And just so of acclimation; its influences ceasing on change of residence, when miasms will be again morbific on returning to the former acclimated region. And so of pleasure and pain (§ 543). The coincidences demonstrate the fallacy of humoralism (§ 665).

551. Again, it is through the principle of vital habit that we must interpret the ability of the system to sustain, with the same or diminished effect, increased doses of remedial agents, as opium, tartarized antimony, &c., while this peculiarity will be limited to the agents which are thus employed. The eighth of a grain of tartarized antimony may produce vomiting at the first dose; but, by gradually increased doses every two hours, it may be sometimes raised in twelve hours, by lessening gastric irritability in relation to its own virtues, to two grains at a dose, without vomiting again (§ 556). But gastric irritability will not be thus reduced in relation to any other emetic. And so of miasmata, &c.; and I may add to § 544, that if the unacclimated pass gradually through a series of climates having gradations of miasmatic intensity, he will ultimately reach its highest virulence with far greater safety than if he plunged at once into its fury. Should, however, epidemic influences occur of an unusual nature, he will still be as much, or more exposed to their malign effects than in uninfected countries (§ 150).

552, a. Other parallels hold, also, in the foregoing cases (§ 551). If, for example, the antimony be suspended for twelve hours, gastric irritability will recover its natural relation to that substance, &c. And so of the miasmatic agent, if the acclimated subject retire to a salubrious region, and subsequently revisit the insalubrious (§ 557, b).

552, b. Again, the antimony impresses the system in the ratio of its action upon the stomach, or of the duration of its action. Fever, or pneumonia, &c., will fail to be assuaged unless the gastric effect be

kept up, if the agent be employed in its small alterative doses. Or a single dose, operating as an emetic, may at once overthrow the disease (\S 524 a, no. 1). And so of miasmata; since, in the case supposed (\S 551), the individual may be gradually brought under its influence, till, at last, its greatest intensity may produce an explosion of disease; or, this may ensue with great rapidity in the same subject if the gradual acclimation be neglected (\S 514 g, 516 c, 518 b, 557 b).

553. No two agents being precisely alike in their effects, habit will vary according to the exact nature of its causes (§ 150, 191, 649). Some, like antimony, often lessen irritability with great rapidity, and the property will recover its relation to the agent after a short interval of suspension. Others as frequently require a much longer time, and irritability will take various intervals of repose, often months or

years, to recover its relation to these agents.

554. It is fundamental in medicine that the foregoing intervals (§ 553) are not long as it respects remedial agents, in their ordinary use, but much longer in respect to the truly morbific causes. In the case, for instance, of acclimation (§ 551), if the subject return to a salubrious climate, it may be many months, or years, before the system will

have recovered its susceptibility to the miasmatic agent.

555. The foregoing exemplification of habit in respect to morbific and remedial agents (§ 554) is allied to the principle which lies at the foundation of disease, and of its cure by remedies, whether physical or mental. Disease consists, essentially, in a more or less permanent alteration of the organic properties; while remedial agents establish more transient alterations, which enables the morbid properties and actions to obey their natural tendency to a state of health.

556, a. Vital habit appears, also, under an aspect opposite to that of diminished irritability. It then presents itself more in the condition of a morbid change of the organic conditions. Thus, tartarized antimony, instead of reducing gastric irritability, as in § 551, may exalt it; so that, beginning with the eighth of a grain, as in the former example, but without an emetic effect, and repeating it without even increasing the dose, vomiting will take place at the second or third dose (§ 514 g, 516 c and d, no. 6). In these cases, we must sometimes progressively reduce the dose to the fiftieth part of a grain, or vomiting will ensue. In this particular case irritability is also increased in its relation to ipecacuanha, and to most other irritants (§ 841).

556, b. This lets us into the philosophy of the most successful mode of overcoming habitual and obstinate constipation, by small doses of cathartic medicine, repeated once or twice daily; as the fourth of a grain of blue pill, and half a grain or a grain of aloes. The irritability of the intestine is thus permanently exalted, by which it is soon rendered so sensitive to the increased quantity of bile as to require a diminution or discontinuance of the medicine. The impression of each dose remains till the next is repeated (§ 514 g, 516 c, 516 d, no. 6). The law of increased susceptibility is brought into operation § 137, d, and alterative reflex action increases the bile (§ 889 l, m).

What I have thus stated in this section involves some of the most important philosophy in medicine. In its practical nature it takes in a wide range of therapeutical problems, some of the most essential of which are relative to the dose or the amount of a remedy, and the prop-

or time for its repetition (§ 857).

556, c. The foregoing principle is farther shown by the effect of saline and other cathartics in promoting salivation when given a few hours after the exhibition of a full dose of calomel. The fact was ascertained by George Fordyce, and has been often verified in my own person after the use of blue pill. The mercurial agent will not exert, in the cases supposed, this profound constitutional effect without the subsequent aid of the other agents, which so increase intestinal irritability, and that of the whole system, that the mercury operates with greater local and general intensity; a fact, by-the-way, which is also opposed to the doctrine of operation by absorption. Just so, too, bloodletting increases the susceptibility of the system to the constitutional and local action of mercury, cathartics, and many other agents, while it also lessens much their doses. A common principle lies at the foundation of the whole (§ 150, 890\(\frac{1}{2}\) g, 892\(\frac{1}{2}\) u, 893 q, 904 c, 1088).

556, d. Augmented irritability, sensibility, and mobility, in their proper relation to habit, depend often upon peculiar states of the stomach, on constitution, climate, &c. Hence in some climates certain remedies, as antimony, are borne much better than in others; cathartics often exalt irritability (especially of the direct seat of action)

in an intense degree, &c.

But other influences in connection with the foregoing are often in operation, and may be the main cause of the effects which are, at other times, due to the causes now supposed. Thus, cathartics are liable to be surrounded by such influences, especially by increased irritability from the presence of disease, or as the effect of passion, or the play of sympathy, or the bile may be increased in quantity or in its stimulating virtues. These modifying influences may be variously

applied.

557, a. The difference in the results of the same remedy in analogous conditions of disease often depends upon, and illustrates, the law of habit. Thus, an emetic and cathartic, exhibited near the invasion of continued fever, will often break up the disease; but not so if the fever have been neglected for twenty-four hours. The morbid action is then under the power of habit. On the contrary, an emetic will often remove an intermittent fever of long duration if administered during the intermission. Here, the febrile action being greatly suspended at regular intervals, the force of habit is constantly broken, and nature puts on its recuperative tendency (§ 555, &c., 715, 926).

557, b. A special exception occurs, however, in the abstraction of blood as it regards its remedial effects upon disease which has acquired the force of habit. In active or chronic forms of inflammation, and in fevers of considerable duration, general bloodletting, particularly, when carried to its just extent, may at once subvert the disease, or, at least, greatly cripple its force and its habitual tendency. Here, an impression is simultaneously and powerfully made upon the whole circulatory system, and that which is thus exerted upon the immediate instruments of disease is greatly advanced by reflex nervous actions from all parts of the capillary blood-vessels (§ 921, 931–934). There is, therefore, a clear analogy in a and b with the modus operandi of miasmata when they prove the exciting as well as predisposing cause of disease near the first moment of their contact with the body (§ 552, b)—philosophically considered (§ 654 a).

558, a. The principle involved in § 556 embraces what is called the

cumulative effect of remedies, and of which digitalis, hydrocyanic acia, mercury, narcotics, &c., supply examples, in their small repeated doses (§ 514, g). And yet some of the same agents, as the narcotics, by longer use, will establish the opposite condition of habit, or that of diminished effect; thus illustrating the different aspects of the laws of vital habit.

558, b. In the cumulative aspect of habit, the agent, as digitalis, or mercury, or cantharides, for instance, establishes progressive impressions on the vital states, proportioned to the amount and frequency of the dose, cateris paribus (§ 926). When that impression reaches a certain degree of intensity, the organic properties are brought into so full a relation with the morbific virtues of the agent, that they undergo, abruptly, a greater change; when the phenomena of full mercurial action, of digitalis, &c., take place suddenly, and perhaps with violence. The last is morbid, and exactly the same as we have seen of the progressive operation of miasmata (§ 552, b). But we often see manifested by digitalis, prussic acid, &c., the same variety of habit as was stated of tartarized antimony in § 551, since we must often increase the dose to maintain the original effect. And so, again, of miasmata (§ 551). This, however, is not true of some of the cumu lative remedies, such as the mercurial (§ 516, d, no. 6).

558, c. And now, to illustrate the alterative reflex action of reme dial agents by the process of removing the morbid effects of the foregoing cumulative remedies (b), we have but to interrogate the only possible manner in which we may speedily subdue those effects by

other remedies, and as explained in $\sqrt[5]{891\frac{1}{2}}$ k, 984 b.

559. Exactly the same philosophy (\S 558) is applicable to what is called predisposition to disease (\S 148, 503, 538, 539, 544, 547, 552 b). Nevertheless, predisposition may differ from the cumulative impression of remedies in being established by a single, and even momentary action of the morbific agent, when the organic states may go on with their morbid tendency till an explosion follows, as in \S 148, 652. So, often, of a single dose of mercury in respect to its curative effects (\S 514, g). But, the difference lies in the greater intensity of the agent, or in a greater susceptibility of the subject to its action, or in both (\S 549, 666, 516 d, no. 6).

560. Another aspect of habit, as it respects morbific agents, and which goes with the rest to illustrate important principles in medicine, is the tenacity of many diseases, as shown in periodical returns of intermittent fever, at intervals of months, even after the subject shall have removed to a climate exempt from the causes. Here the original impression remains (\S 514, g), and frequently, also, some local form of disease, by which the general predisposition is maintained,

and its explosions more or less produced (§ 148).

561. What concerns the acquired habits that appertain more or less to the constitution of all men, and which have a modifying, and often a great, influence in determining the operation of morbific and remedial agents, comes entirely within the foregoing principles relative to vital habit; and this is more obviously true of the accidental modifications of temperament that arise in individuals from the influence of climate, heat, cold, &c. (§ 78, 442 b, c, 535, 539). Where the peculiarity of constitution is transmitted from parent to child the modifying causes have, of course, operated upon the ancestor. But the

transmitted peculiarity is equivalent to that which is generated by the direct action of the modifying agent (§ 75-80, 585, 587, 591, 659).

Here, too, we may observe how the incubation of fever, for a week or for months, is analogous to the slow progress of the artificial temperaments; though, in the former case the remote causes may operate for an hour only, and thus establish a tendency in the organic properties to advance in their morbid predisposition, till, reaching a certain amount of change, a development of fever is suddenly displayed; while, in the artificial temperaments the changes are commonly the result of the continued operation of the remote cause.

562. The luxuries and customs of civilized man affect his natural constitution upon the same principles as morbific agents produce disease, or as the remedial alter the properties of life back again to a state of health. In all the cases, the results are owing to impressions variously made upon the properties of life (§ 191 b, 535, 539).

563. So simple is Nature in her elementary laws that the periodical desire of food, and many little usages of the body, fall, more or less, under the comprehensive law which I have exemplified by prominent instances of habit. And here, too, we glance at the philosophy of instinct in its magnificent relations to certain natural habits; and realize, also, in the phenomena, the principles which are concerned in the analogous relations of the will to voluntary motion (§ 500, c-h).

564. In my last proposition I was on the borders of *education*, which is mostly confined to animal life, or extended to both where animal

and organic are associated in functions.

Education is allied to habit in its philosophy, as manifested both in the cultivation of muscular power and the properties of the mind

(§ 175 b, 241).

565, a. Education often improves some of the animal functions at the expense of others; but this mostly where some are more the subjects of cultivation than others, as seeing, hearing, &c., or the muscular action of the arms, &c. (§ 539, c). When one sense, as sight, is extinct, others, as hearing and touch, become very exquisite. In the case of the muscles, mobility is augmented, and their nutrition increased; in that of the senses, sensibility.

565, b. A more critical analysis, in the case of the muscles, shows us that mobility in organic, and its modification in animal life, are both advanced (§ 205, 215). Hence result the increase of voluntary power and the increased size of the muscles. By this muscular exercise the function of digestion is also increased, the elaboration of bile, and important vigor is imparted to the whole organic mechanism. The principle is exactly the same as in all the preceding ex-

amples relative to vital habit.

566, a. This chain of exact analogies brings us to the properties of the mind, which are improved upon the same principle (§ 175 b, 241, 565). Here, as in the foregoing instances (§ 565), one or more of the properties is apt to be exalted at the expense of the rest (§ 539, c). The poet, therefore, thinks differently from the man of cultivated judgment; the lawyer is prone to sophistry and skepticism; the mathematician is wrapped in abstract truths, and deficient in practical business; the clergyman, from his well-disciplined trust in Revelation, and his scholastic habits, suffers that trust to degenerate into credulity, and too

often patronizes homeopathy, or delights in animal magnetism, or even in the anti-scriptural speculations of the geologists. The history of nature is nothing to the chemist out of his laboratory; in physiology he is like the astrologer among the stars. Shall I speak of the physician? It is said by Samuel Johnson that he is more apt to cultivate all the powers of his understanding, and all departments of nature, together, and that he has therefore been more distinguished for an enlightened and comprehensive view of the various subjects for reason

than any other class of mankind.

566, b. And now we are prepared to comprehend the analogies between those impressions which are brought about by the habitual action of external objects upon the senses, and in which the mind is concerned, as in the satiety of spring, the increasing enjoyment of painting, sculpture, and music, and the increasing acumen with which their beauties and refinements are discerned, and, also, those other changes that are incident to the organic properties from the habitual use of tobacco, of stimulants to the nose, to the stomach, &c., or such as arise from tartarized antimony, acclimation, and those moral influences through which the black skin, the low forehead, and the flat nose, are rendered more beautiful to the African than the analogous features of the white man, or which render the flattened head, and the scarified face, an ornament to the eye of the American Indian, or the deformities of the corset, or the artificial rump, elegances in polished society, while the few that worship at the Graces' shrine become objects of dislike. The same fundamental philosophy obtains through-

567. From the foregoing analogies between the mental and vital powers (\S 566), it appears that the former are cultivated through the medium of the senses and brain, and as well by external influences as by the operation of the sensorium commune, upon the same principle that the vital properties are influenced, more or less permanently, by the operation of foreign agents (\S 175 b, 241). The impressions in respect to mind, however, are more complex, since, in this case, they

come to the spiritual part through material organs.

568. We may now see the nature of the analogies between the special injuries which result from too much or improper food in the early stages of life, and crowding the mind with study or with topics beyond its easy comprehension; and those between the ultimate adaptation of the properties of the stomach to what was once offensive, and the corresponding development of the properties of the mind and of its organs by which it sustains what had been detrimental to both, and to the general health. These principles lie deeply at the foundation of a proper elementary education of the mind (175 b, 548½ b, 567).

STRENGTH, AND WEAKNESS OR DEBILITY.

569, a. Much of what has been now considered under the various aspects of habit is often vaguely defined by the terms strength, and weakness or debility. The terms are without any true meaning, and have led to very extensive practical errors. If the finger become inflamed, muscular action is impaired in the hand, or arm. This is called weakness, debility, both of the vessels which are engaged in the motbid process, and of the muscles. But, bloodletting, either general or by leeches, will cure the disease and restore muscular action.

Here the nature of the remedy contradicts the supposed philosophy

(§ 743, 801, 964).

569, b. Strength and debility are, also, often confounded, leading to still greater confusion and error. Thus, manifestations of full muscular power are said to denote strength, while the high vascular action of inflammation is supposed to depend on debility. The former is also often seen in deplorable states of disease where debility is thought to reign supreme. On the contrary, also, the mere prostration of voluntary motion at the very invasion of disease is as constantly considered a state of debility, however exalted may be inflammatory or febrile affections upon which that contingency in animal life may depend. Tonics and stimulants, therefore, have their sway according to these supposed imaginary conditions,—imaginary, since disease consists neither in one nor the other, so far as they have any intelligible import. The designations, for the most part, are borrowed from the inorganic world; and even at this day some physiologists are making experiments upon the dead muscular tissue by immersing it in solutions of tonics and astringents, to learn the value, and the modus operandi, of those agents when applied to morbid states of the living being. Dr. Adair Crawford, for example, in his Experimental . Inquiry into the Effects of Tonics and Astringents (1816), attributes their influence entirely to the tanning process, by which physical co-hesion is established. His premises are those upon which the illustrious and able Pringle, and his compeers, rested the same conclusion; animal membranes having been immersed in various infusions, and comparisons made of their resistance to weight with the same membranes soaked in water. Strength was implied in the former instance (§ 487 h, 1001-1008, 1019, 1068).—Notes Ff p. 1135, It p. 1139.

569, c. If strength and weakness, or debility, be applied to organic states, it must be in a totally different acceptation from their ordinary meaning. In their vital applications, they can relate alone to any present condition of the vital powers. In this sense, the greatest strength of the body consists in a natural performance, by all the organs respectively, of the functions appropriate to each, without either borrowing from the others any assistance which it does not constitutionally enjoy, and without taking upon itself any undue amount of labor. In a state of undisturbed health, and temperate habits, the functions of all organs move on in harmony, each administering to the others a certain allotted contribution. But, in impaired constitutions, the whole of this natural harmony is more or less disturbed. Digestion is imperfectly performed, and every meal tasks the stomach beyond its natural ability. The other organs suffer, sympathetically, in consequence, and often seem to bend their actions toward a co-operative effort in aid of the diseased actions of the stomach. In this sense, therefore, all the powers of the system may be said to be unnaturally tasked. But, in the mean time, all the sympathizing organs are themselves afflicted, and just in proportion as they sympathize with the The food escapes from this organ in a half-digested state, in which chemical changes have also occurred. These changes beget acids and flatulence, and, as the crude mass traverses the intestines, it irritates, and increases the sympathetic derangement of those organs, while these, again, reflect back pernicious influences upon the stomach and all other parts. Increased and unnatural mucus, diar-

rhœa, &c., follow in the train of intestinal symptoms, urged on by an unhealthy production of bile; while an offensive taste in the mouth, a foul breath, or a coated tongue, tell us of the sympathies which are going on in that region. The red or turbid urine shows us that the kidneys have joined in the disordered actions. The pulse may be languid, or it may beat high, according as inflammation may be absent, or have set in as one of the sequelæ; but according to the accidental state of this symptom the degree of weakness is greatly measured in this complex and very common condition of disease (§ 423). But, whatever the symptoms, the system is said to be weak, to be debilitated. There is, however, no truth in this construction, as it is ordinarily understood. The powers may be all exalted; and that this is generally so, is shown by the increased secretions from the liver and intestines; while it is fully demonstrated by the nature of the curative means, which consist especially of a low diet. The supposed debility is nothing but an altered condition of the properties and functions of life, and the very remedies which the idea of debility would suggest, such as stimulants and tonics, are generally aggravating causes. Such is the exaltation of irritability, especially in the intestinal canal, that it may not bear even the stimulus of broth, nor the mechanical irritation of solid food.

569, d. The nearest approach to the popular sense in which debility is properly applied consists in the exhaustion of the organic powers that attends the advanced stages of prolonged disease.—See § 487 h.

So far, therefore, as debility has an existence, and as connected with disease, it is nothing but a symptom resulting from some modified condition of the functions of one or more organs, in which the true pathological cause consists, and to which alone our remedial treatment should The humoral terms anamia, leucamia, cachexia, and be addressed. chlorosis, in their connection with iron and debility, are, therefore, responsible for an incalculable amount of mortality. But as I have said, much of this symptom (always mostly so in the early stages of disease) is owing to the failure of the Will to act upon the voluntary muscles (§ 487 h, 961); and when this circumstance is duly considered it may result in a profitable inquiry into the probable extent of mortality that may be ascribed to the tonic and stimulant treatment of disease (§ 621 a, 1001 a, 1065 c, 1068 a). No writer who has discarded loss of blood as a principal remedy for inflammations and congestions, or inculcated "the stimulating plan," has survived his own generation excepting John Brown, and his work exists only as a curiosity in medical literature (§ 1068 a). The practice is perpetuated by individual prejudices and impulses (\$ 960 g), not by the authority of enlightened or recognized experience, nor by any thing in the pathology of disease (p. 872).

569, e. Finally, I may conclude this subject with the nervous language of Southwood Smith (On Fever): Thus—even "in the intense forms of congestive fever, I look upon the notion of debility to be an error not less palpable in its nature, than destructive in its consequences; and if the havoc it produces do not confer upon it a pre-eminence as bad as that of the very disease of which it is supposed to constitute the essence, it at least entitles it, in comparison with every other error in medicine, to the distinction recognized in society between the hero and the murderer. The one destroys a single human being now and then, but the other numbers its victims by thousands."

FIFTH DIVISION OF PHYSIOLOGY.

MODIFICATIONS OF THE VITAL PROPERTIES AND FUNCTIONS ARISING FROM AGE, TEMPERAMENT, CONSTITUTION, SEX, VOLUNTARY HABITS, &c.

570. The differences among individuals, and classes of mankind, which arise from age, sex, temperament, &c., may be regarded in the light of qualifications of the four preceding grand attributes of

organic beings.

571. Organic beings are liable not only to permanent changes in their constitution from external influences, but to others of an inherent nature. Constitution and temperament supply examples of the

former; age and sex of the latter.

572. These changes (§ 571) consist in varying conditions of the properties of life, and possess, therefore, not only important relations to the physical agents of life, but modify, according to their different circumstances, the operation of morbific causes, and our therapeutical treatment.

573. All the foregoing conditions spring from the natural instability of the vital properties; and such as are brought about by external influences involve exactly the same philosophy that is concerned in vital habit (§ 177, 539). Under the present division of Physiology, however, the modified conditions are, in a general sense, of a far more permanent nature than such as I have assigned to vital habit.

I. AGE.

574. As our bodies undergo progressive changes from the time of birth to the end of life, the duration of human existence has been divided into five periods; namely, 1st. Infancy; 2d. Childhood; 3d. Youth; 4th. Adult or middle age; 5th. Old age. They mark the times during which the greatest physiological changes take place.

575. The differences which grow out of age consist in variations of the external form, and of the forms and density of the internal parts, of variations of structure, and of natural modifications of the vital properties and functions. Upon these last depend all the other chan-

ges (§ 153–155, 237).

1. INFANCY.

576, a. Infancy extends from the time of birth to the end of the first dentition.

576, b. At this age the fluids predominate. The organs are now softest. The bones are imperfectly ossified. The muscles small. The arteries are as numerous as in the adult, but more capacious. The cutaneous veins small, while those of the brain, and some other internal organs, are well developed. The skin warm, thin, and delicate, covered with soft hairs and underlaid with fat, which, in the adult, is removed to the internal viscera; acute in irritability, obtuse in sensibility. The eyes are large, but inobservant, resting, for the most part, on dazzling objects. The organ of hearing is imperfect and dull, and attracted only by acute or loud noises. The nose small

and irritable, sensitive in the nasal branch, but dull in the olfactory. Taste indiscriminate. Sensibility and irritability are highly developed in the intestinal canal. The teeth are making their way, one after another, till at the end of two and a half years, the first dentition is completed. Digestion and nutrition are in rapid progress, and the secretions and excretions copious. The appetite great, and returns almost as soon as appeased. The development of the digestive system keeps pace with the progress of the teeth, and when eight or ten shall have appeared, the stomach is ready for a gradual change of nutriment. The limbs are feebly controlled. Sleep is often repeated and long continued, being scarcely interrupted for the first week, even by hunger, so powerfully is the new being under the influence of its fætal habits. Few mental impressions being made there is no trouble from dreams. Sleep is therefore calm while the organs maintain their healthy round. It is all sleep or all wakefulness, with but little of the revery of later years. The pleasures are sensual and without alloy, but very limited. The gratification of appetite is the highest enjoyment, and hunger the greatest suffering. Judgment and reflection are in a dormant state. The mind is easily irritated, but as easily appeased; and crying is as natural and salutary as laughing at a later age.

576, c. The most important peculiarities of infancy, physiologically, pathologically, and therapeutically considered, are the general imperfect development of sensibility, and the greater general development of irritability, mobility, and sympathy, than at any other period of life.

576, d. As the diseases of infancy, like other ages, correspond with the physiological characteristics (§ 155, 156), they are not liable to be aggravated by causes which operate through common and specific sensibility; but the greater development of irritability, especially of the brain and intestinal canal, than at any other period of life, subjects the infant to a predominance of cerebral and intestinal diseases. It is owing, also, to this physiological condition of the alimentary canal that any excess of food is readily rejected by the stomach. But irritability, in being thus susceptible of the influences of the natural vital stimuli, that all its contingent purposes may be fulfilled, is especially liable to morbific impressions (§ 137 d, 150). It is owing to the imperfect development of the cutaneous veins in infancy, and childhood, that there is an absence of varix; and, on the other hand, cerebral congestion and hydrocephalus are now common, because the cerebral veins, and the brain itself, are large and highly endowed with irritability. Croup also prevails, and is more or less attended with a production of coagulable lymph, because of a peculiar natural modification of the organic properties of the mucous tissue of the larynx, which changing at later periods gives rise to catarrhal inflammation (§ 134, 135). Morbid sympathies are common and strongly pronounced, especially between the intestinal canal and the skin, and between the former and the brain. The sympathies, however, are mostly on the side of the skin and the brain, the primary affections being in the intestinal canal. Next, the lungs are liable to pneumonia, but most so after dentition begins. The appearance of the teeth is attended with some new physiological conditions, and dentition aggravates or gives rise to intestinal derangements, disturbs the natural sympathies of organs, and provokes convulsions of the voluntary muscles (§ 526, d).

576 c. Diseases being rapid and active in infancy, and injurious sympathies speedily and powerfully determined, it is obvious that remedies must be prompt, decisive, and of quick operation. But, it is also an important consideration that nature is now strongly recuperative; that the same physiological susceptibilities of infants to disease, and to its rapid advances, render them also peculiarly sensible to remedial agents, when timely and happily applied; and that they now operate speedily and with power on account of the great development of irritability, mobility, and sympathy (§ 150). Hence it is, that milder means which fail at adult age may succeed under apparently the same circumstances in infancy. An emetic, therefore, or cathartic, or alterative doses of tartarized antimony, &c., may become a substitute for a certain quantity of blood, whose abstraction in the same condition of disease would be indispensable at adult age; or leeching may be sufficient in the former case, when general bloodletting would be necessary in the latter. But, since the dangers of disease are greater, and there is less time for delay, in the diseases of infants than of adults, we should be sure of the right before we decide on neglecting or procrastinating the more vigorous treatment. This observation, however, is intended to apply especially to the abstraction of blood. Active internal remedies should be delayed in cases of doubt. On the other hand, an early loss of blood is far less likely to be detrimental; and where it may be required, but delayed, the chance of its useful application may be lost, not only through the advances of disease, but by the prostrating effects of other remedies (§ 155, 156, 925 a, b, c, 964 d, 974 c, 1058 p).

576, f. It may be finally said of the characteristics of infancy, that the first few weeks of independent life are marked by peculiarities which go to illustrate the philosophy of life as expounded in these Institutes. Sleep, for example, is remarkably continued; cutaneous sensibility so dormant that injuries of the surface are scarcely felt, &c. But it is in organic life that we meet with functions that are destined for speedy modifications, of which the generation of heat is

the most remarkable (§ 441, b).

2. CHILDHOOD.

577, a. Childhood extends from the age of two and a half to fifteen or seventeen years in males, and to fourteen or sixteen in females.

577, b. Irritability, and the other organic properties, become modified, and variously, in different parts. Those of the brain settle down into that modification which is only necessary to established functions (§ 156); or, at most, do but undergo slighter changes at the subsequent periods of life. Consequently, the brain sheds a new influence over other organs; and irritability, being less strongly pronounced in all other parts than in infancy, they are less disposed to sympathize with diseases of the brain, and of each other, or the brain with them. The digestive system has undergone manifest changes; and here, too, irritability is particularly diminished. Solid food has become indispensable, while it was inadmissible in early infancy; is less frequently desired, and can be digested only when taken at longer intervals. The secretions and excretions have lessened, as a consequence of the changes in the organic states.

Sensibility, especially specific, had made advances in infancy, and increases rapidly in childhood. The various organs of sense are turned with increasing attention to surrounding objects. This denotes an increase of perception and with it the other mental faculties hold a progressive but more cardy pace. As knowledge pours in, the faculties of the mind increase in an increasing ratio. The organs of speech are unfolded, and there is great volubility of tongue. The skin has become less delicate, and the sub-cutaneous fat has undergone diminution (§ 440 bb, 440 c, no. 11½, 441 c). The chin loses its double character, and the general features acquire a contour in which that of infancy is nearly lost. They reflect the operations of the mind, and beam with enjoyment when not disturbed by the angry passions that now spring up along with knowledge and reason.

577, c. The foregoing new state of things gives rise to new diseases, or to new modifications of infantile diseases. Morbific causes operate according to the new modifications of the vital properties. There are new and modified circles of sympathy (§ 156, 566). New parts become the seat of disease, as the ligaments, the mesenteric glands, the lymphatic glands, the joints. Disease, too, is now apt to result in disorganization, from which infancy is greatly exempt. have seen that some diseases become less frequent, as those of the brain. The diminution of intestinal irritability lessens the frequency and force of abdominal derangements; and this relative exemption cuts off that exuberance of sympathies which was displayed in the intestinal irritations of infancy. Croup disappears at the age of twelve. Among the new causes of disease may be reckoned the passions, and the new avenues of external influences through the senses; though the absence of grief and the predominance of hope are favorable to childhood. This is the age when severe mental labor does its worst with the constitution.

577, d. Remedial agents bear a general relative correspondence with the new physiological conditions, like the morbific, as we have seen of infancy, varied, however, from the latter by the modifications induced by disease (§ 149, 150).

3. YOUTH.

578, a. Youth extends from the end of childhood to the age of

twenty or twenty-five years.

578, b. As the characteristics of infancy pass by imperceptible degrees into those of childhood, so do those of the latter gradually fade into the condition of puberty. New phenomena are alike presented by the mind and body; all springing from natural modifications of the same powers which conducted the development of the ovum through all its stages to that of the infant; which carried along the exact vicissitudes of infant life to that of childhood, and which transform the child into a being capable of procreating his species. The developments of structure go hand in hand with those of the vital powers, the latter always taking the lead, according to the ordination of the Creator; and for Whose direct Agency, as exerted at the beginning of organic life, these formative powers are designed as a subordinate substitute,—always fashioning the new being according to the original model (§ 63, 64, 155).

The most remarkable peculiarity by which youth is introduced is

the development of the organs of generation, which, as in plants, may be regarded, in a physiological sense, as the great final object of the development of all the other organs from the embryo state; new beings being thus produced that other new ones may follow. Such, then, being the ultimate tendency of all the physical and vital developments, it obviously follows that a new condition has taken place in all the animal and organic powers at the age of puberty, and that the development of the generative organs will, in their turn, so modify the conditions of life as to carry out the design of nature in perpetuating the species.

578, c. Specific sensibility is now at its acme of development, and its corresponding mental power, perception, is in full and rapid operation. Knowledge of external things pours in as rapidly as the eye can glance from object to object, or the ear distinguish the tones of music as they run into each other. The mind now seizes this knowledge, and appropriates it more extensively than before to the improvement of its own powers. It compares phenomena with each other, observes their resemblances and contrasts, and as the judgment, under this exercise of reflection, acquires maturity, it deduces the great laws by which the phenomena are regulated, and finally carries them up to the very powers from which they emanate. But it does not so clearly follow that the provision which nature has made for the right government of the mind or the body will be duly employed. No sooner, indeed, are we born, than abuses begin,—if not on the part of infancy, on that, at least, of its natural guides and protectors. stomach is crowded with solid food instead of its natural fluid, or when solids become appropriate the least appropriate are often selected. The properties of life being thus abused, they suffer, and not unfrequently perish in consequence. The passions, yea, even anger, are designed for our happiness or for our protection. But judgment is permitted to fail of its legitimate sway, and the passions are let loose to fill us with disease, to imbitter our corporeal and intellectual existences, to incarcerate our bodies, or to hang us upon the gallows.

Coming to the abstract operations of mind, do we not find a like abuse of the understanding? Do we not constantly find that the knowledge which has been acquired is perverted to the worst conclusions? Are not the phenomena of nature which are opposed to each other made to assume resemblances, and such as are clearly allied equally estranged? And do we not then, by this abuse of reason, proceed to refer these incongruous results to common laws and common causes? We need not go beyond the subjects before us for an affirmative answer. Are not all the unique phenomena of life, all those which mark the distinctions between infancy, childhood, and youth, all those which attend the consummation of the body for the development of the generative organs, for the production of the ovum, of the seminal fluid, even sexual desire itself, and its ultimate termination in new beings, ay, the very thoughts which go up to Heaven, most extensively referred, at this thinking, speculative age, to the forces which rule over dead, inorganic matter? But there is a stage of human existence, which that modified materialism that acknowledges a soul has not yet dared to invade. That stage begins when both parents infuse themselves into their future offspring, when a new soul, like a new body, is generated; and it extends throughout the fætal development. The same processes, as we have seen, are now in progress as at every subsequent stage of life. The same powers, therefore, and no others, are alike at all times the causes of the coincident

results (§ 65-76).

Returning to the characteristics of youth, we find that the testes now enlarge, and secrete the seminal fluid; the uterus becomes rapidly unfolded in its powers and structure; the menses take place: and, in both sexes, the arrangements for generation are established. While these peculiar changes are in progress, sensibility and irritability are acutely susceptible, and give rise to restlessness, impatience. and often to anxiety and distress, without absolute disease. mammæ also prepare for the work of nutrition, swell out, and assume that peculiar rotundity which is considered the beau ideal of beauty. The beard puts forth. The face swells with blood, that the features may be supplied abundantly with the material which is necessary for their full development; and it is now that physiognomy begins to take its rank among the sciences. The muscles obtain greater firmness, greater power, and greater action. The cutaneous veins enlarge beyond their former capacity. The organs of speech undergo another change, as denoted by the hoarse and rough voice. The body spreads, becomes firm and erect, and often shoots up, in early youth, with amazing rapidity.

So much elaboration of structure, and the institution of the generative functions, cannot fail, according to our doctrine of life, as sources of many new reflex nervous actions, of new diseases, or modifications of former disease. The principle, indeed, is fundamental, that diseases vary according to the natural variations that may spring up in the vital states of different parts, or of the entire body, at different periods of our existence (§ 150, &c.). These fluctuations of the natural states of the system, as also disease itself, and its very cure, as we have seen, grow out of the natural instability of the properties of life (§ 177). The natural instability, or liability to definite changes at the progressive stages of life, is ordained not only for the new physical developments that are taking place, but also for certain incidental conditions, such as gestation, lactation, &c. (§ 155, 156). Will chem-

istry explain?

We consequently find that the concerted action of organs is liable to be disturbed at the beginning of youth, independently of disease. The heart beats irregularly, respiration is hurried, or slow, or laborious, and fluctuates as the passions rise or fall, or as the mind may happen to poise; and the heart, and the cutaneous vessels of the face, obey the same influences. These susceptibilities may be more or less extended to all other parts, without the intervention of disease. Among these physiological results are frequent bleedings of the nose, headache, constipation, and partial disturbances of digestion. So, also, is that pain and distress which attend menstruation, and all the reflex nervous influences which are inflicted upon the system at large during the progress of this excretion. It is the vital, not the chemical powers, which are thus disturbed, but not morbidly affected (§ 237).

578, d. Where, however, nature introduces so much novelty there must be new diseases, and new sympathetic results of a morbid character. And now mark the coincidence between the progressive development of the vital states and their liability to morbid affections. The uterus, for instance, has hitherto been merely in a vegetative

state. It has had no specific function, and its organic properties have existed only in that condition which is essential to nutrition. This organ, therefore, has been scarcely liable to any disturbance, not even of a sympathetic nature; for the organ, hitherto, has taken no part in the general operations of the body. And how clearly this illustrates the laws of reflex nervous action in their application to disease, and exposes the absurdities of the humoral pathology! But, as puberty arrives the uterus takes on its specific function; and, that this may be performed there must be a great modification of the organic life of this organ. Agreeably, therefore, to the universal law the uterus must be now liable to direct disease, and to morbific reflex nervous actions from diseases of other organs; while primary diseases of the uterus, in their turn, develop sympathetic affections in other and distant parts. Diseases of the digestive organs inflict diseases upon the womb, and menstruation is suspended as one of the consequences. Again, when the uterus is most actively engaged, as during menstruation, it should, according to our principles, be most liable to disturbance, either from the direct operation of foreign causes, or from reflex nervous influences of other diseased organs. Accordingly, even exposures to a chilling atmosphere, damp and cold feet, &c., will so disturb the uterus, when engaged in excreting the menses, as to arrest its function. And what are the frequent consequences? A long chain of sympathetic diseases, which, from the beginning of their primary cause, we might as well attempt to explain by lunar influence, or by the ebbing and flowing of the tides, as by any principle in the humoral pathology, or by any laws that rule in the world of dead matter. And yet does the intellectual world abound with physical hypotheses of life and disease for the interpretation of phenomena of which those now under consideration are only simple elements. Now, too, the mammæ, for the first time, have their organic powers brought forth, to be in readiness for the secretion of milk. And mark, as we go along, the harmony of Design, and the coincidence between the preparation of the mammæ and that of the uterus. The development of the latter takes the lead, while that of the mammæ is the work of sympathy, and this ascendency is maintained in the pregnant state. And yet we are told that final causes should have no place in philosophy. But the mammæ, like the uterus, now, and for the first time, become the seat of morbid conditions; and, from what we have seen of their natural relations to the uterus, we readily comprehend the reason why they inflame when the uterus undergoes its sudden and violent change in parturition, and why the secretion of milk is now started, and why they are liable to diseases, such as carcinoma, which, at least, seldom occur before this organ is brought under the uterine influences (§ 138, 524 b, d). How forcibly do all such problems admonish the chemist and physical philosopher to regard all others relative to life, in its natural and morbid conditions, as a part of that great whole, of which the former are only more striking examples!

Again, the testes now, also, for the first time, have their vital state so modified as to perform their function of secreting semen (§ 155). Of course, therefore, for the first time, these organs should be liable to morbid affections, should now, for the first time, sympathize with the diseases of other parts, and inflict reflex actions upon dis-

tant organs. But, besides the general functions, susceptibilities, and influences in which the testes, the uterus, and the mammæ now participate in common with other organs, there are some special characteristics relative to each part that reflect no little light upon our doctrines of life and disease. The development of the testes, for example, exerts a powerful reflex nervous influence on the changes which are simultaneously going on in other parts, as denoted by its well-known effect upon the voice. If the parotids be invaded by mumps, the testes and mammæ are liable to inflame by sympathy, &c. The natural and pathological conditions harmonize together; the latter being strongly associated through the nervous system with the new developments of structure and modifications of the vital states, all of which are owing essentially to alterative reflex nervous influences unceasingly excited by the evolution of the generative organs (§ 516 d, no. 6).

From the vital elaborations which are in progress about the face. it is liable to eruptive affections, and the throat to inflammation. Articular rheumatism is now more rife than in childhood, and more so than at any other stage of life. If disposition to scrofula exist, it still manifests itself, as in childhood, in the lymphatics of the neck; but now, especially, it invades the lungs. This, therefore, is the age for tuberculous phthisis. The brain, having already nearly acquired its plenitude of development, and moving on in quiet stability of its organic powers, and the mental faculties employed in undisturbed operations, is comparatively exempt from disease. The passions, it is true, are now at work; but they are not of the morbific kind, either as it respects the brain or distant organs. Anger is the worst, but goes off in explosions. Envy has not been whetted. Grief is transient. Malice has not had its incentives. Avarice awaits the maturity of judgment. Hope and love hold a sway over the whole, and these are conducive to health, when love does not run into excess. Nevertheless, there are transitions from excessive hilarity to the gloom of melancholy, and the mind by fits is fanciful, and by fits is dull. But, by more than all things else, it is subject to depressing influences from the development of the generative organs, and this in proportion to its rapidity; and the state of the mind, as to its dullness, is an index of what is in progress for the procreation of the species. When the organs of generation have attained their maturity, the mind acquires its equilibrium; and its faculties, by this process, have obtained an immense accession to their vigor. These influences are alike felt by both sexes. As youth approaches the adult state, the body, like the mind, increases in vigor, and is capable of all the labor of maturer years. Now is the period for athletic exercise, and feats of strength, and now the awkwardness of youth subsides into the gracefulness and dignity of manhood (§ 237).

4. ADULT OR MIDDLE AGE.

579, a. Manhood begins at the age of twenty to twenty-five, and

reaches to about sixty years.

579, b. At the beginning of this age, all the faculties of the mind are approaching their state of maturity. "He," says Zimmerman, "who, at thirty years of age, is not an able minister, an able general, or an able physician, will never be so." The stature of the body is soon completed, its form perfected and all the organs fully devel

oped. We have, therefore, but little novelty in disease during the age of manhood, except such as may spring from the operation of new accidental causes. The buoyant hilarity of youth is succeeded by greater steadiness of mind, tempered by sobriety and judgment. The passions are now in full operation, and those of the worst kind become more strongly pronounced; of which, avarice and envy are predominant. The disappointments and the trials of life have become manifold, and fall with their heaviest effect; and, as one succeeds another, hope is more or less supplanted by anticipation of evil. The passions, therefore, at this period of life, are of a morbific nature, and lay deeply the foundations of disease, or embarrass the operation of our curative means, and the salutary efforts of nature. Diseases of the digestive organs, especially, and their sympathetic results, are the frequent consequences of grief and disappointment. And, although the appetite has diminished, and is less frequent than at former ages, habits have become more artificial, temperance gives way to excesses, and the activity of youth yields to sedentary pursuits. Numerous arts, and the seductions of the study, call us, also, from the genial influence of the open air, and in various other ways, contribute morbific influences.

Most of the injurious tendencies which are superadded to the age of manhood beset, in the first place, the organs of digestion; dyspepsy being one of the most frequent forms in which disease is now presented, and carries in its train a multitude of sympathetic evils. It is not, however, till the age of thirty-five that these manifestations become common, unless the foundation have been laid, as is frequently the case, by violations of nature in childhood or in youth, or by transmitted predisposition. This is also the period of pregnancy; and, although a natural condition, the artificial habits of society have so modified the natural state of the system, that pregnancy, parturition, and the period of nursing, give rise to no small amount of disease. For the same reason, also, menstruation is often interrupted. while this interruption deranges other organs. Owing, in no small degree, to these acquired peculiarities and the diseases of women, midwifery has become a distinct and important department of medicine. From forty-five to fifty menstruation ceases, and with it the period of childbearing. This new change in the uterus is apt to develop sympathetic disturbances in other parts, and to become a cause of disease in the uterine organs. But, as a compensation, there is now an exemption from those maladies and that suffering which result from the menstrual function.

From the age of 45 to 70, the cerebral veins take on that peculiar modification of congestion which results in a secretion of blood, and which, as occurring in the brain, determines the common form of apoplexy. This condition decreases toward the age of 70. But, I shall not dilate farther upon the peculiarities of this era of life, since they are all referable to the great principles which govern the characteristics of every other period, and all require the same considerations in the aspects of pathology and therapeutics. As at all other stages of existence, also, the characteristics of manhood are gradually changing till they are finally blended or disappear in those of old age, or that stage of life when it is very erroneously supposed that "the machine is wearing out" (§ 237, 581 b, 584 b, 633).

5. OLD AGE.

580. The last period of life has been subdivided into incipient or green old age, which extends from 60 to 70; confirmed old age, or caducity, from 70 to 85; and decrepitude, from 85 years, upward.

581, a. More remarkable changes now take place in certain parts of the organization than from the beginning of youth upward; but, as they occur not in the essential organic parts, modifications of the organic properties and functions are less the cause of certain prominent phenomena than the physical deviations in comparatively unessential parts; such as ossification of the cardiac valves, of the arteries, &c. The senses are failing as an avenue of knowledge. The eye becomes dim, and the ear is only arrested by acute, or distinct, or loud noises. The motions of the body are slow, the back stiff, and more or less curved. The intervertebral cartilages, also, shrink, and the stature lessens in consequence. The joints and tendons become rigid; the sutures coalesce; the skin is darker and more wrinkled; the fat retires from the circumference to the internal organs, by which the superficial veins are rendered more prominent, and the eyes sunken.

581, b. Nevertheless, rigidity and other changes go on in the most essential organization, which are principally characterized by a natural decline of the vital properties and functions; but none are abrupt, and there are no new functions introduced, and none are arrested. All these new conditions, too, as at all other stages of life, are the work of the organic properties,—always creative, but ultimately giving rise to physical changes of a suicidal nature, and which end in their destruction. Irritability and sensibility are, therefore, upon the wane, and mobility is alike embarrassed by the foregoing physical changes. The nervous system has mostly played out its part.

581, c. The mind, too, in ordinary cases, is going with the organic powers; but it is worth observing, as a characteristic distinction between the soul and the organic properties which animate its abode, that genius rarely wears out. It sparkles as bright as ever when the

flickering lamp of life is but dimly seen.

581, d. The decline of the mental powers is accompanied by a subsidence of the passions; and as sensibility also fails, former morbific causes and avenues to disease are thus greatly diminished.

581, c. The old man waits his certain doom in calm serenity, or only impatient for its approach. He is satiated with the pleasures of life; perhaps because he can enjoy no longer. His reminiscences are rather of his pains than of his delights, because the former are more indelibly established, and are not now counteracted by present

enjoyments.

582. From what we have now seen of the physiological conditions of old age it is evident that diseases vary but little from those which prevail after 40 or 45 years; only from the gradual embarrassments sustained by the organic powers disease is apt to be less violent, while, also, for the same reason, there is less of the recuperative ability. Apoplexy, palsy, organic affections of the heart, and urinary difficulties, are the predominating accidents of old age.

583, a. Although, therefore, morbific causes are less energetic in old age than at other stages of life, remedial agents are, also, less op-

erative, nature less recuperative, diseases less easily arrested, are sooner beyond the reach of art, and often eventuate suddenly in death, without having attained any degree of severity. Life often snaps when the old man is quaffing his wine, or as he "shoulders his crutch to show how fields were won."

583, b. Hence it is apparent that remedies must be prompt and efficient in proportion to the exigencies of disease; as is more exten-

sively set forth in the article on Bloodletting (§ 1014).

584, a. Finally, it appears from the characteristics of life at its various stages; the progressive variations in the vital states; the successive developments of important organs; of the new functions which are instituted and again extinguished; till we come to that period when the properties of life lay the foundation of their own ruin by instituting disorganizations of structure; and from what, also, we have seen of the corresponding modifications of disease at the various eras, and of the new ones which appear, with their new train of sympathies, it is obvious, I say, that there must be some corresponding variation of treatment which may be relative to a common character of disease (§ 117, 134-160). But, at every varying stage of life, all things proceed upon established laws; and, however modified the powers which may be in operation, and by which every result is brought about, and whether so by nature, or by morbific causes, or by art, there are precise laws by which all the phenomena are determined according to the particular combination of existing circumstances. It is an important object of art to find out all the conditions which may attend any given state of the properties and functions of life, whether natural or morbid, that the most appropriate regimen may be adopted, or remedial agents be applied with the greatest precision. In all this the nervous system demands a critical attention.

584, b. Every remedy would always operate in one uniform way, were the conditions of the vital properties and functions, and the structure which they animate, always the same; just as the blood always affects the heart and vessels in one uniform manner, in health. But, such is the instability of the properties of life, and such, in consequence, the variableness of morbid conditions, that these modifications are rarely precisely the same in any two instances, or at any two successive days. To find out these varieties, and to adapt accordingly the general principles of treatment, and in their relatively specific details, is one of the highest and most difficult aims of medicine; and demands, as an indispensable qualification, a profound knowledge of the phi-

losophy of life.

II. INDIVIDUAL AND GENERAL PECULIARITIES, CONSISTING OF TEMPERA-MENT, CONSTITUTION, IDIOSYNCRASY, AND NATIONAL ATTRIBUTES.

A. Temperament, Constitution, Idiosyncrasy.

585, a. Under our fifth division of physiology we have next in order the *Temperaments*, &c., or those peculiarities of life which naturally distinguish one individual from another. The temperaments, therefore, may be regarded as embracing the innate as well as acquired peculiarities of constitution; for, although the latter depend upon causes that are relative alone to the individual, the former, or innate constitution, has been brought about, at some anterior genera-

tion, by the physical agencies of life. This is the true temperament,

and belongs to masses of mankind.

585, b. Idiosyncrasy is only a variety of temperament and constitution, and like those, therefore, depends upon some peculiar modification of the properties of life, especially irritability; but only so in relation to a very few particular agents. It is peculiar to individuals, rather rare, and may be hereditary or acquired. This peculiarity is not unfrequently the cause of the favorable or deleterious effects of certain remedial agents, of certain kinds of food, &c. We see the important principle illustrated every day, every hour. Here is a subject who is salivated by the external application of a few grains of mercurial ointment, and in whom syphilis, or fever, may be speedily extinguished by this simple use of the remedy. But here is another, in whom the internal administration of an ounce of calomel may produce no constitutional result, and make no impression upon syphilis. Or, it may be in another case of extreme susceptibility to the action of mercury, that the agent always displays the effects of a profound poison, aggravating fever and syphilis, or, in the absence of disease, greatly deranging all the functions of life. Most men are poisoned by the slightest contact with the rhus vernix; but now and then an individual handles it with impunity. Muscles, and some other animals, are always poisonous when eaten by some people, though generally good articles of food.

585, c. Constitution comprehends all the peculiarities of the individual,—the temperament, idiosyncrasy, conditions relative to age, sex, habits, &c. It is therefore liable to many variations at all periods of life. The prevailing characteristics of each of the elements may remain, but yet so modified that what is known as constitution may be

"broken down."

585, d. The same principle is concerned throughout, whether in respect to constitution, temperament, or idiosyncrasy. It is the same as prevails habitually in respect to the naturally modified irritability of different organs in man, and in all animals, and in plants; that which renders urine innoxious to the bladder, but morbific to all other parts,—that which renders the eye susceptible to the undulations of light, the ear to the undulations of air; and so on (§ 133–159). The principle, and its everlasting, unchanging laws, are every where, in all that relates to organic beings, whether in respect to the system in its abstract condition, or as relative to external agencies. It is a great and wonderful principle, a perpetual study for the philosopher, ever pregnant of variety, ever illustrative of the peculiar character of the properties of life, of their natural modifications, of their instability, and forever supplying fresh sources of interpretation of the laws which the properties and actions of life obey.

586. It is evident, therefore, that temperament, constitution, and idiosyncrasy, are constituted by certain acquired or transmitted conditions of the vital properties, which form a part of the natural or habitual state of each individual, and from which arise various degrees and kinds in the susceptibilities to the action of physical agents, and certain peculiarities, also, in the material condition and conformation of parts, especially the external. By studying these sensible peculiarities, as well as the phenomena of life in their natural and morbid conditions, we infer the peculiarities of the natural vital conditions in dif-

ferent individuals, or their natural constitution and temperament, or any more remarkable idiosyncrasy. They reach, also, to the mind, which is apt to bear certain relative peculiarities to those of the organic states.

588. In the farther consideration of this subject, I shall regard those peculiarities of constitution which are mostly of a determinate nature, and include them under the general denomination of temperament.

589. The physiological differences between temperament, idiosyncrasy, and constitution, are neither great, nor of much practical importance. Indeed, so allied are they in principle, that a common philosophy determines the remedial treatment, which is always more or less modified by temperament. Each should be considered along

with the modifying influences of habits, climate, &c.

590. Temperament and constitution do not depend, as supposed by some writers, upon the special development of particular organs; though this is true of some of the vicissitudes of age (§ 153-159, 596). The former have their foundation in the system at large, and are apt to be transmitted by one or both parents; or the transmitted peculiarities may come from a remote ancestor, and not from the immediate progenitor. This last peculiarity is analogous to one of the characteristics of the scrofulous diathesis, where it passes over one

generation and reappears in the third.

591. It appears, therefore, that temperament, whether innate or acquired, is due to the slow operation of causes upon the vital constitution; just as we have seen of the law of vital habit (§ 535-568). In the latter case, the modifications are more or less transitory; but may be so ingrafted as to be transmitted, for a time, like the permanent temperaments, from parent to child, as seen of some diseases, such as lues, or of predispositions to disease of a transient nature, as in smallpox, or even ordinary fever. Coming to hereditary disease of a permanent nature, as scrofula, we run from the transitory phenomena of vital habit, by an intimate analogy, into the permanent temperaments; and from these we are conducted by the same philosophy, which respects the operation of physical agents in modifying the properties of life, to those more remarkable peculiarities which spring up in animals from domestication, and in plants from changes of climate and soil (§ 75-80, 143-147, 220, 327-331, 559, 561-563, 659, 666 b, 674).

592. It is scarcely probable that differences in temperament have, often, any appreciable effect on the elementary composition. Differences, however, obtain in respect to structure, as seen in the general form, the proportions of the limbs, the features, &c.; while more remarkable corresponding analogies are witnessed in the herbaceous and arborescent habits of the same plant, as it may be subject to the influences of a tropical or cold climate, as the ricinus communis (§ 538).

593. Great differences arise not only in respect to the influences of the same remedial agents from the mere circumstances of temperament, but morbific causes may be equally various in their operation. The same causes may also be very apt to affect one temperament, while they will rarely have an effect on another temperament (§ 142 145,740). The nervous system is much interested in those modifications.

594. The temperaments, as designated by the ancients, and retained by the moderns, are divided into the sanguine, the melancholic,

the choleric, and the phlegmatic. The artificial habits of the moderns

have added a fifth, or the nervous.

595. It is not usual to find all the attributes of each temperament united, while some of the whole may be blended in the same individual. Nevertheless, the characteristics of one or another generally predominate.

596. Temperament is most distinctly pronounced at adult age, af-

ter the influences of development have ceased (§ 590).

1. THE SANGUINE TEMPERAMENT.

597, a. Unlike the other temperaments, the characteristics of the sanguine are perpetuated from infancy, and perhaps, therefore, may be considered the most natural. The skin remains soft and delicate; the limbs rounded and full; the superficial veins, unlike those of infancy, large, conspicuous, and blue, especially about the head and temple; the complexion fair, florid, and animated; the eyes large and

blue; the hair light, or red, or of intermediate hues.

597, b. Sensibility and irritability are strongly pronounced; the great development of the latter giving the principal determination to the sanguine temperament. The blood, in consequence, stimulates the heart to more frequent, high, and regular action, maintains the capillaries in a lively and plethoric state, and thus determines the redness and softness of the skin. Other vital stimuli also operate with greater intensity than in other temperaments. For the same reason, the secretions and excretions are rapid and copious, and are little liable to vacillation, in the ordinary conditions of health. All things else move on in a corresponding manner; the whole assemblage of which beautifully illustrates the true philosophy of life.

The great development of sensibility contributes, also, its considerable part to this temperament. The senses are ever on the alert; and here, as with irritability, external objects make their impressions with great effect and rapidity. Perception is rapid, reflection quick, imagination lively, memory prompt. The succession of ideas is too rapid for comparison, and hence the judgment is infirm, unless associated with genius; when it is distinguished for eccentricities. This is exemplified in the poet, Byron, and in the warrior, the Marshal Duke of Richelieu,—"that man, so fortunate and brave in arms, light

and inconstant, to the end of his long and brilliant career."

597, c. Inconstancy and levity are the great moral attributes of the sanguine. Variety and enjoyment never satiate. Devoted to sensual gratifications, they are in love with all female beauty, and are inconstant to a mistress, if not to a wife; yet are they honorable in all things else. It has been said of Newton, that he was of the sanguine temperament; but, had he been so, it is replied, "he never would have carried, as he did, his maidenhead with him to the grave, at the age of fourscore." Nor do the senses afford that leisure for profound meditation, nor admit of those intellectual operations which are indispensable to the mathematician and astronomer; whose habits, also, are more adverse to this than to any other temperament.

The sanguine is eminently generous or prodigal, and the end of gain is the purchase of pleasure. Quick in anger, he is soon cool; or he is impelled to hasty decisions that are soon regretted. A challenge to a duel would be gladly abandoned, did not a sense of pride

urge him on to the combat. Revenge and envy have no hold upon this constitution.

597, d. It is evident, therefore, that the prevailing diseases of the sanguine temperament are active and inflammatory; that the organs sympathize readily and greatly with each other, and that the sympathetic affections are disproportionately greater than the primary affections. Infancy always partakes of this temperament; but if it be truly constitutional, the infant is liable to extraordinary demonstrations of its fundamental nature. The irritation of a tooth, for example, is more apt to produce convulsions, and intestinal derangements still more so, or to lay the foundation of cerebral disease, &c. At adult age, slight disturbances of the womb bring on hysteria, or indigestion contributes to a more sudden accession, more violent phenomena, and a more rapid progress, and lights up the flame of other diseases more speedily, and more violently, than in other temperaments. Anger, being quick and vehement, here displays its instant effect in developing inflammations, and hemorrhages. But love is too instable to undermine the health; and as envy, grief, and jealousy, torture not the mind, so do they not the body. The nervous system is in lively force. 597, e. As external causes, whether natural or morbific, make

597, e. As external causes, whether natural or morbific, make their impressions rapidly and profoundly upon the sanguine temperament, and its diseases being active and violent, remedial agents should be prompt, and decisive, as in infancy; but here, also, for the reasons which are relative to the first period of life, and for such as are assigned in section 597 b, remedies are also profound and speedy in their operation. And since the prevailing disease of this temperament is inflammation, bloodletting is the principal means of cure, and will require but little co-operation from other agents. If early applied, and carried to its proper extent, it will often nearly extinguish the most violent inflammations during its first application. The test of this extent will be also more exactly determined in this than in other temperaments by the subsidence of symptoms during the progress of the operation. It is in this temperament, also, that the philosophy of the vital influences of loss of blood is most evidently shown (§ 191), and morbific and therapeutical aspects of reflex nervous actions.

2. THE MELANCHOLIC TEMPERAMENT.

598, a. The melancholic temperament has certain points of resemblance to the sanguine, though they are strongly contradistinguished. The general external aspect of the latter is cheerful; that of the melancholic, dry, stern, or gloomy, and excites no liveliness in others, though it command respect and even admiration. The solids predominate in the melancholic; the capillaries show less blood, though the veins are large and more prominent, but less transparent than in the sanguine; and, unlike the latter, the skin is darkish, or inclining to yellow, thick, coarse, and hard to the lancet. The blood flows more freely from the sanguine when the skin is pricked; and this exemplifies the state of the capillary circulation at large. The same principle obtains, therefore, in the pulmonary circulation, and hence, in part, the blood is darker in the melancholic than in the sanguine. The eyes of the former are darker and less prominent than in the latter; and the hair is dark, coarse or stiff; eyebrows large, black, and often projecting; the muscles and tendons, like the superficial veins

stand out, from the absence of that cutaneous fat which gives rotun dity to the body of the sanguine (§ 440 bb, 440 c, no. 11½, 441 c).

598, b. It is easily seen, therefore, that irritability and sensibility are comparatively dull in the melancholic. External objects do not make the strong and rapid impression upon the senses as in the sanguine; and, from the obtuseness of irritability, the action of the heart is slower, the capillary blood-vessels are less charged with the vital fluid, the secretions and excretions less, and more slowly performed (§ 191). The nervous system evinces great stability of functions.

598, c. The melancholic temperament is the principal abode of genius; embracing a large proportion of those great men who have unfolded the laws of nature, or have made the highest advances in the arts, or have astonished the world with deeds in arms, or with the achievements of the statesman, or the orator, or the painter, or the poet. The melancholic is the man of men. I had almost said, in moral constitution, he is perpetuated, unchanged, from the model of his race. Here is witnessed the highest intellectual renown at the very dawn of manhood; and here it is that we so often meet with genius struggling with those adversities which arrest the ambition of other temperaments. The melancholic is forever indomitable; rising in determination as obstacles rise before him. Inflexible in purpose. the passions are disciplined to urge on an arduous enterprise, or if allowed to become impetuous, it is to accomplish the decisions of the understanding. With equal facility he concentrates his mind upon abstract inquiries, or at the next moment sends it abroad over the widest theatre of its operations. He is bold and brave, never fearing death, nor wantonly incurring danger. He moves steadily forward, though he does not move till the path before him has been explored. His imagination, therefore, is of the highest order, being disciplined by the sterner faculties. It is such an imagination as is always an element of genius; such as contemplates the realities of life and the truths of Revelation. He is thoughtful, grave, or sad, but may tune his mind to great elevation and great sublimity and enthusiasm, and often soars on poetic wings through the regions of Heaven. The sanguine, on the contrary, delights in the romance of fiction.

Honor holds its empire in this temperament, however it may be wauting in human sympathies. If pledged to a good or a bad action, it is fulfilled. The melancholic is generally fervent but dignified in his attachments, or looks with indifference or with scorn upon humanity. A few, like Tiberius, are fearful, perfidious, suspicious, and cruel; and others, like Nero, or Richard, insensible to danger, and

ever ready for the work of death.

598, d. As with sensibility and irritability in their natural aspects, so is it in their relation to morbific and remedial agents. The coincidence is universal. The former are slow in establishing morbid changes, many are inoperative which readily light up the flame of disease in other temperaments; and the passions, a prolific cause with others, are subdued by the melancholic into mere agents of the un derstanding. But when morbific causes have made their impression, the dullness of irritability and mobility explains why disease is apt to be obstinate, and why remedial agents operate with less rapidity than in the sanguine. The vital properties and functions being slowly susceptible of morbid changes, they are slowly altered from their morbid states, and with this coincide the actions of the nervous system.

It is easily inferred that the diseases of the melancholic are mostly of the digestive organs, and that their removal is tedious. It is also manifest that these, and other affections, are slow in developing diseases of other parts, and that the brain and the mind must be most likely to sympathetic disturbances. Hence it is that hypochondriacism and insanity are apt to supervene on the melancholic temperament.

Cathartics are demanded more by the melancholic than by any other temperament; though their exigencies have a special relation to the disorders of the digestive functions. Bloodletting, also, is often necessary to reach these chronic maladies; and, although its delay in the grave forms of inflammation be less hazardous than with the sanguine, its necessity is as great, and its extent and frequency of repetition are greater. It is here, too, that the greatest demand is made upon the materia medica for auxiliary means.

3. THE CHOLERIC TEMPERAMENT.

599, a. The *Choleric* is intermediate between the sanguine and mel ancholic temperaments; and although it form the sanguineo-melancholic, it possesses characteristics which give to it an individuality.

The skin has greater fullness of the capillaries than in the melaucholic, and therefore greater softness, and warmth, but less than in the sanguine. The pulse is intermediate in fullness and frequency. The secretions and excretions moderate and uniform; the healthy

functions performed with regularity and ease.

599, b. The passions are easily roused, though not impetuous, and therefore less transient and less easily appeased than in the sanguine, though not so persevering as in the melancholic. The choleric is tenacious of his own rights, but less disposed to infringe upon the rights of others than the melancholic, while he has less generosity than the sanguine. The higher faculties of the mind correspond with the other characteristics of this temperament, being generally distinguished for their moderation.

599, c. Irritability and sensibility holding an intermediate degree between those of the sanguine and melancholic, external agents operate with a relative effect and rapidity; so that the organic functions move on without frequent or profound interruptions, and diseases yield to a more compound treatment, though less readily than to the simpler means required by the sanguine, but more speedily than in the melancholic.

4. THE PHLEGMATIC, OR LYMPHATIC TEMPERAMENT.

600, a. The *Phlegmatic* is characterized by slothfulness of mind, and by a simpler display of vegetative life than any other temperament. The flesh is soft, the countenance pale, the hair delicate, and the fat amounts to an encumbrance. The limbs are rounded, feeble, and without expression. The veins are small, and lie deep. The pulse is small, feeble, and soft; arteries small, and the capillaries deficient in blood. Irritability is dull. The secretions and excretions are performed slowly, and their products are thin or watery. Sensibility is also obtuse, and perception weak, which greatly circum scribes the senses as an avenue to the mind; while

"Fat holds ideas by the legs and wings"

But, with all the intellectual dullness and bodily indolence which distinguish this temperament, it is obstinate, fearful, suspicious, and avaricious. The nervous system is blunt and on the side of evil.

600, b. The organic properties of the phlegmatic are easily liable to interruption, though morbific causes, unless intense in their nature, make their impressions feebly. The mind, and its predominant passions, have, of course, but little agency in the production of its diseases. Disturbances, however, seem to arise from the mere inertia of the vital powers; and when morbific causes make strong impressions the properties of life often go down at once to near the verge of extinction. So, also, do active remedial agents operate with a relative effect. Emetics are scarcely admissible; violent cathartics prostrate excessively; and any unnecessary extent of bloodletting breaks down the whole energies of the body. This temperament, therefore, requires great moderation of treatment (§ 150).

5. THE NERVOUS TEMPERAMENT.

601, a. The Nervous temperament displayed itself feebly among the ancients, but has been brought to a high maturity by the progress of civilization. It is the only temperament where the primary causes may be traced, which consist mainly of such as are attendant on indolence and sedentary pursuits. It involves alike, therefore, the rich and the poor, the sensual devotees of fashion and the plodding shoemaker, the laborious student and the readers of romance.

601, b. The nervous temperament is founded upon the sanguine, or the sanguineo-melancholic, and is either transmitted, or springs up originally in the individual. It is therefore the most artificial of all the temperaments, and is susceptible, individually, of great improvement. It is shown externally by a general aspect of feebleness, a spare body, and small, soft muscles, which are incapable of much ex-

ertion.

601, c, Disturbing reflex nervous actions are the leading characteristic. Irritability is also strongly pronounced. Hence, slight disturbances, even of unimportant parts, give rise to greatly disproportionate sympathies in the more important organs; and these secondary results will be still more intense if the primary disease be seat-

ed in any important organ.

The functions are constantly subject to irregularities, especially those of the abdominal viscera. If the subject be addicted to the causes of this temperament he is rarely free from indigestion, and an attendant train of other evils, according to the nature of his indulgences or pursuits. Diseases, however, are not as violent as with the sanguine, nor as profound as with the melancholic. The mind is irritable, but the passions not violent, though they readily disturb the organic functions. Such as display themselves depend much upon the habits and occupation of the subject.

601, d. Remedial agents operate with power; the same coincidences existing between their effects and those of a morbific nature, as in other temperaments. Moderate impressions, therefore, made upon the intestinal canal are sensibly felt by remote parts; and in this temperament, particularly, the peculiar principle upon which leeching

operates is well illustrated (\$ 145, 147, 914, &c.).

General Remarks on Temperament.

602, a. Different epochs of life appear often to partake of a particular temperament; one subsiding into another. The sanguine is most characteristic of infancy and childhood; the melancholic and

choleric of middle age; and the phlegmatic of old age.

602, b. The several temperaments are also often blended, more or less, with each other in the same individual, though the characteristics of one generally predominate. When combined in the same individual, they are called the sanguineo-melancholic, the sanguineo-phlegmatic, &c. They are also liable not only to the foregoing modifications from age, but from sex, climate, habits, education, &c. So great, indeed, is the influence of climate, that a change of residence (as from a northern to a tropical country) will sometimes gradually transmute one temperament into another; and this is particularly true of the sanguine, the melancholic, and the choleric.

602, c. The foregoing accidental influences are sometimes such as to generate anomalies, in which it is difficult to recognize any distinct features of the prevailing modifications of temperament, and which may disappear with the individual, or be transmitted to his descend-

ants.

602, d. All the varieties comprehended in this section are more or less liable to modifications of a common form of disease, and require corresponding variations in the details of treatment. They concur together, therefore, in forming a part of the difficulties of medicine, and in demonstrating the complete abstraction of organic beings from the

forces and laws of the inorganic (§ 659).

603. I say, organic beings in their most comprehensive sense (§ 602, d). For are not the varieties which have sprung from domestication, and cultivation, among animals and plants, and which are equally, and more perfectly transmitted than temperament, constitution, &c., in relation to man, integral parts of a common principle? Exactly the same philosophy lies at the foundation of the whole, and is another broad field of evidence to substantiate the unity of the Vital Principle, of its common laws and functions throughout animated nature, and presents the whole in a magnificence of Grandeur, a Harmony and Unity of unfathomable Designs, which stamps an unutterable contrast on the confusion and imbecility of the chemical and physical hypotheses of life. (See Climate.)

B. Races of Mankind.

604. Corresponding, in principle, with Temperament, &c., though different in their manifestations, are those peculiarities which have distinguished mankind into various Races. They correspond more nearly, in the physical characteristics, with those sensible changes which are established by the domestication of animals, and by the cultivation of plants (§ 603). As with many species of the latter, the varieties of mankind have existed without change as far back as history begins its record. This circumstance has often led the speculative mind to imagine as many original ancestors as it may distribute the human species into varieties of race (§ $350\frac{3}{4}$, kk). But, with exactly the same reason may we ascume that the black and the white barn-yard fowl, and all the other varieties of this animal, or the red

and the white potato, and other varieties of this root, the sloe and the plumb, the crab and the apple, are equally distinct, and that each has descended from a distinct original progenitor. Or take the yet more remarkable transmutation of a salt and bitter weed into the varieties of the cabbage and cauliflower by transplanting it from the sea-shore into the rich mold of gardens, and which are as dissimilar as each from the original species.

605, a. The attributes of Race are mostly of a physical and moral nature; and, unlike the temperaments, but analogous to the foregoing varieties of animals and plants (§ 604), they are not attended by any special modifications of the properties and functions of life; but all the races are liable, individually, to the physiological conditions of temperament. The general attributes, therefore, admit of no physiolog-

ical, pathological, or therapeutical applications.

605, b. And here it is worthy of remark, as illustrative of the common nature of the properties and functions of life, that other changes to which animals and plants are liable from unaccustomed physical agents are attended by distinct modifications of their vital states, and remarkable variations of structure. An animal, for example, transferred from the tropical to colder regions, undergoes a change in its hairy or woolen vesture, or from summer to winter in the same climate. The tree, transplanted from the tropics to a northern latitude, may be made to resist the inclemencies of winter, and finally puts on a denser bark, and a hibernaculum for its leaf and flower-buds. Or yet more strikingly, what is herbaceous in equatorial regions may become a shrub or a tree in temperate climates. These mutations, therefore, are strictly analogous to the temperaments of man. Or, again, what is more emphatically characteristic of the analogies of nature in any of her grand departments consists in the fact that the varieties which are constituted by hybrid animals and plants are, equally with the foregoing, both in respect to cause and effect, corresponding phenomena with the varieties of temperament (§ 72).

606. From what is known of the analogous varieties among different species of animals and plants (§ 604), we shall have little difficulty in referring the characteristics of race to the influence of physical agents upon the properties of life; and of these there are none so obvious as climate. Like temperament, &c., the whole falls under the

laws of vital habit (§ 535, &c.).

607. Perhaps there is no better classification of Race than Lacépède's; who reckons only the European Arab, the Mogul, the Negro, and the Hyperborean. These have been variously subdivided.

Blumenbach's division of the races is also simple and just; namely, the Caucasian, the Mongolian, the Ethiopian, the American, and the Malay. The Caucasian variety answers to the European Arab of Lacépède; the Mongolian to the Mogul; the Ethiopian to the Negro; the American embraces all the natives of North and South America, excepting the Esquimaux; and the Malay includes the inhabitants of Sumatra, Borneo, New Holland, and many other islands of the South Sea; most of whom speak the Malay language.

608. The European Arab comprises the people of Europe, Egypt, Syria, Arabia, Barbary, Tartary, Persia, the North American In-

dians. &c.

The fundamental characteristics are an oval face from forehead to

chin, a prominent skull anteriorly, a long nose, skin more or less white, and long, straight hair.

609. The Mogul race is composed of the Chinese, the inhabitants of Eastern India, Tonquin, Cochin China, Japan, Siam, and the South American Indians. This race is more numerous than all the others.

Its characteristics are a flattish forchead, eyes turned rather obliquely outward, cheeks prominent, oval face between the two cheek bones.

610, a. The Negro, a native of Africa, possesses the most perfect characteristics. The black skin, the low, flat forehead, the depressed nose, the thick lips, the crisped hair, the dullness of understanding, and the acuteness of his senses, mark him as the greatest phenomenon among the physical changes of our species. This is the only race of whom it can be surmised that the change has been miraculous.

610, b. The bondage to which the Negro has been subjected has naturally excited the sympathies of the humane, and has led them to assume in his behalf an ideal rank in the scale of mind. I would not oppose this harmless prejudice were it not in collision with fundamental laws which it is my duty to interpret, as far as may be, as nature teaches. The brain has sustained in this degraded race (degraded as well by nature as by man) that failure of development, which, as universally admitted, stamps the white man with intellectual inferiority. But, degraded as is the Negro in mind, in body, and in bondage, he is yet a man, and, like the rest of the human family, descended from common parents. His very imbecilities, therefore, entitle him the more to our sympathies and protection (§ 1078, s).

611. The Hyperborean stands, also, in strong relief from the rest of mankind. This race comprises the Laplanders, the Esquimaux,

Samoiedes, Ostiacs, Tschutski, &c.

They have broad faces, flat features, swarthy skin, and are stinted in growth. In the scale of intellect they rank next above the Negro.

III. SEX.

612. Certain physiological differences in the sexes appear to have been impressed originally upon the constitution; and this, indeed, was necessary to the perpetuation of the species. But, although our first parents were created in a state of maturity, there were ingrafted upon the constitution (§ 64 &c.) the laws of development for natural growth, and which are designed to conduct the individual to that mature condition in which he came from the Hands of the Creator.

613. Besides the special difference in the organs of generation, woman is of a lower stature than man, less rigid in organization, softer and more delicate in her skin and complexion, abounds more with cutaneous cellular tissue and fat, (§ 440 bb, 440 c, no. 11½, 441 c), which gives greater rotundity to her limbs and greater concealment to the muscles. Laws of nervous system more strongly pronounced.

Her mind is quick in its operations, arrives earlier at maturity, but is less vigorous, than in man. The passion of love, although indomitable, is more a sentiment with her than with the other sex. She seems, however, especially designed for the reproduction of the species, and for the early care of her offspring.

614. Sensibility, irritability, and therefore mobility, are more exquisite than in the male, and, for a like reason, she is more susceptible, as with the infant, and the sanguine and nervous temperaments,

to the action of morbific causes. Sympathy predominates, also, in the female; and hence local diseases are more apt, than in the other sex, to disturb other parts. But she is not, therefore, more liable to death; since the vital powers being more strongly pronounced, they are more recuperative, and the same susceptibility to morbific causes renders her, also, more susceptible of the genial effect of remedial agents. What Providence has denied to one, He has given to the other.

IV. CLIMATE.

615. The influences of climate in modifying the physiological character of man are great and various, and still greater and more various in predisposing him to disease. The physiological effects of climate are also strongly shown in animals, though often far less in their organic than their animal economy; while in the vegetable tribes these or analogous results are often strongly manifested in organic life. The nervous system takes its usual modifying share (§ 578 d).

616. I shall speak now mostly of those permament effects of climate which are known under the denomination of temperaments, for the purpose of illustrating still farther the radical changes which may be established in the vital states by physical agencies (§ 585–603). This, also, will show how profoundly climate may operate in disposing the organic functions to a state of disease, and will contribute, with what has been said in other places, in inducting us into a knowledge of the philosophy which relates to predisposition to disease.

617. The extremes of heat and cold are conducive to the formation of the sanguine temperament, either in maintaining it as an inherited peculiarity, or in developing it out of other constitutions. But, it is mainly the dry heat of the tropics which goes to the formation of the sanguine temperament. The phlegmatic and sanguineo-phlegmatic belong mostly to warm climates, especially to such as are moist. The choleric and melancholic occupy the temperate regions; and here, therefore, we may look for the demonstrations of genius. The choleric and melancholic gradually merge into the sanguine, or phleg-

matic, in tropical regions (§ 1047).

618, a. The philosophy of life, as already expounded, enables us to comprehend the manner in which the foregoing transitions and varieties are brought about; while the changes confirm that philosophy (§ 617). Thus, when the melancholic migrates from the temperate to a tropical climate the uninterrupted and powerful action of heat upon irritability and sensibility renders these properties more and more susceptible to the action of blood, and all vital stimuli. The secretions and excretions become, in consequence, more abundant; morbific and remedial agents manifest corresponding variations in effect; and since, also, the organic properties of the brain sustain the modifications incident to other organs, and the senses acquire greater liveliness, the whole character of the mental faculties takes on that of the sanguine temperament, and what was once an uninterrupted effulgence of mind dwindles down to occasional scintillations. This is especially the course of the transplanted melancholic if the temperament incline to the sanguine. But here, as with the choleric, or where the sanguine and melancholic are distinctly associated, if the temperament lean to the phlegmatic the vital properties are rather depressed by heat, and the functions of the body and mind are more slowly and feebly performed; being influenced even by the vicissi-

tudes of season, and by the daily atmospheric changes.

In the tropics, therefore, man is indolent, given to pleasure, and lives only for himself. With the natives of high northern latitudes the properties of life are under the perpetual influence of cold, which fails, in consequence, of its usual action as a stimulus in temperate climes, and all the functions are slowly performed; save only the generation of heat, which has its special final cause. Growth must therefore be slow and stinted, and there must be (cæteris paribus) great capability of resisting morbific causes, and a gradual recovery from disease. As the temperate climates hold an intermediate rank in their vital relations, it must be here that we shall find mankind representing the most perfect attributes of their nature.

618, b. The same philosophy holds in respect to animals and plants, since all observation teaches that they are as sensibly affected, in certain aspects, by the diversities of climate, as the human race; being, also, like man, subject to modifications from education, soil, &c. (§ 605, b), allowing for differences in organization and life (§ 185).

619. We thus see that climate contributes largely to the formation of temperament, and exerts direct modifying influences upon the general character of disease. In this last acceptation it embraces all the predisposing causes which appertain to different regions; such as the various kinds of miasmata, temperature in its general aspect and as liable to vicissitudes, moisture and dryness, and other obvious conditions. Physiological principles lie at the foundation of the whole.

620, a. From the considerations which have been now made, as well as for other reasons, chronic diseases should abound in the temperate zones, while they are comparatively rare in equatorial climates. Consumption is a grand characteristic of the former, especially of the

sea-board and other humid regions.*

620, b. The principle about which the facts just stated are concerned, as well as others that are relative to climate, is well illustrated by the rapidity with which the chronic maladies of horses yield to tropical influences; a large proportion of these animals which are destined for the West India markets being thus affected, and thus relieved.

621, a. The remarks which have been now made in respect to climate lead me to indicate an important duty of the physician as it respects the inhabitants in an individual sense; though I have in view its philosophical as well as practical bearing.

True, it has been lately stated on the authority of the British Army Statistics, that consumption is more rife on the West India stations than in any other quarter of the globe; from which the conclusion was drawn that the disease was especially incident to those climates. This important fallacy I have pointed out in the Medical and Physiological Commentaries (vol. ii., p. 619-622). In that work, also, especially in the Essays on Bloodletting, and on the writings of M. Louis, I have set forth the facts, which, with the preceding, and others of a coincident nature, enforce the importance of rejecting all army statistics, and other hospital reports, as forming any proper foundation for great pathological and therapeutical conclusions; and have endeavored to show that all such conclusions should be drawn exclusively from the private walks of the profession, where the constitution is natural, the habits good, and disease early and judiciously treaded, and where, especially, the superintending physician is, bona fide, the prescriber and critical observer, and more anxious for the recovery of his patient than for a post mortem examination. Hospital reports represent nature in her most distorted aspects, the treatment of disease being often begun at its moribund stages, and when the system is full of organic lesionsthis treatment, too, often experimental, and without reference to fundamental physiological principles (§ 623).

The native and the acclimated are apt to possess very different susceptibilities from the new-comer, from which it results that the treatment of their diseases, respectively, should be more or less governed by these considerations; while it will be, also, the important business of the physician to point out to the stranger the means of averting the new morbific influences to which he is subjected, and his modified susceptibilities. The means are various, and of the highest moment. It was from their neglect, as I have shown, that the mortality from consumption has been so great upon the West India stations, and the Report of which has led to so many theoretical and practical errors (§ 620, note). And as to the importance of a proper adaptation of treat ment to the acute forms of disease upon the same military stations, it is only necessary to consider the appalling contrast between the results of practice as introduced by Robert Jackson, and that which im mediately preceded his superintendence as surgeon-general. By diminishing, also, the allowance of "salt beef and rum" to the sick, he saved the British government \$400,000 per annum. And who does not know that it is the same now as in Zimmerman's day? "I know," says Zimmerman, "a certain Esculapius who has fifty or sixty patients every morning in his antechamber. He just listens a moment to the complaints of each, and then arranges them in four divisions. To the first he prescribes bloodletting; to the second a purge; to the third a clyster; and to the fourth change of air! The same vulgar prejudice leads people to have a great idea of the practice of large hospitals. I have seen, in my travels, some of the largest hospitals in Europe; and I have often said to myself, Heaven, surely, will have pity on these miserable victims" (§ 1065 c, 1068 a).—Note Fp. 1114.

621, b. In connection with the foregoing should appear the modifications which arise from peculiarities in the specific nature of the remote causes of disease, which are almost as various as the causes themselves. We know, indeed, that the pathological cause of inflammation may be varied by the manner in which wounds are inflicted; and more various, therefore, must be the exact modifications which are determined by agents which possess specific properties. To know those modifications presupposes, in no small degree, a knowledge of their special causes. They demand a great versatility of treatment where common principles may apply; and this may be determined more by a knowledge of the remote causes than by any resulting phe-

nomena (§ 644, &c.).

V. HABITS, OR USAGES.

622. It now remains to speak briefly of the last subdivision of our fifth grand division of Physiology. Under the denomination of Habits are included the various pursuits of mankind, their social and political relations and institutions, their modes of living in respect to food, exercise, clothing, &c.; with a special reference to their physiological and pathological influences, which are great and numerous.

Much of this subject is considered under the direct physiological aspect of vital habit (§ 535, &c.), and the same principles obtain throughout. The usages of man not only variously modify his vital condition in a transient manner, but, like the effects of climate, incompatible habits may establish permanent and transmissible changes of constitution. The glass-blower, the brazier, the painter, the type

setter, &c., have, respectively, modifications of a common disease, which are still different from those of the sedentary divine, lawyer, and shoemaker. And so of the various pursuits which demand more

or less exercise in the open air.

623. Habits, in their most extended sense, open upon us a field for endless observation. Here it is, in the neglect of the natural means of preserving health, in the pinches of poverty, in the filth of indolence, in Bacchanalian indulgences, and in the various resources of licentiousness, we meet with nature so turned from her physiological condition, that when disease sets in it presents the most embarrassing anomalies. The hospitals of all countries, especially of Europe, show a disgusting amount of these artificial deformities. And yet are they sent forth as legitimate grounds for important conclusions in pathology and therapeutics (§ 620, note).

All the foregoing varieties of disease, which grow out of deleterious habits, or pursuits, may yield to the substitution of natural means,

or to change of employment.

624. As to the active treatment of the cases last recited, I can only say, that, while the great principles obtain as in less artificial states, they demand greater modifications of practice than all other special conditions that are incident to man. But, let us remember, that when we meet with phrenitis, or pneumonia, or any other grave inflammation, ay, or even erysipelas, affecting the most broken-down constitution of the most dissolute man, stimulants will be pernicious, and he must

take his chance from a modified antiphlogistic plan.

625. Under the category of habits may be arranged the modifications which are exerted upon the constitution by subdued diseases. There are many affections which leave their subjects not only unusually susceptible of morbific agencies, but modify the pathological character of the diseases which may subsequently spring up. The dyspeptic affections that follow recoveries from fever are more obstinate, and require a more varied treatment, than such as arise from simple indolence, or even from high living. Syphilis, though cured, predisposes to an obstinate form of rheumatism, which requires a different detail of treatment from that which is induced by cold, or by

hepatic and intestinal disease.

 $625\frac{1}{2}$. The usages and habits of man supply a fruitful field of inquiry into the modifying influences of the nervous system upon his organic states, and for tracing out their analogies with those reflex actions which contribute to the development of structure, and most remarkably at the age of puberty, when the evolution of the generative organs, starting in the same inscrutable laws of organic life as are provided for the analogous organs in plants, establishes that profound labyrinth of reflected nervous actions which bring under their sway the whole animal fabric, and through which we may look as a guide at all the more obscure relations of the nervous system to the organic fluctuations of man and animals, even the exalted grade of their organic compounds, and to which influences are owing, in part, the peculiarities that distinguish the animal from analogous conditions of the vegetable tribes; while, also, we may find in the same pronunciations of the generative organs a clear physiological ground for interpreting the modus operandi of morbific and remedial agents and the multifarious influences of organs upon each other either for good or for evil (§ 514 g-m, 578, 896 902 i-m).

SIXTH DIVISION OF PHYSIOLOGY.

THE RELATION OF ORGANIC BEINGS TO EXTERNAL OBJECTS.

626, a. That division of physiology which concerns the relations between living beings and external nature is very comprehensive, and brings into immediate connection the three great departments of medicine; and it is an object of these Institutes to consider the subject under this limited aspect. Here it is that these several branches meet together, and here it is that we learn that pathology and therapeutics are only modified aspects of physiology. They are all immediately interested about the properties of life; physiology regarding the healthy influences of external agents upon those properties, pathology their morbific effects, and therapeutics those changes which are exerted upon the morbid properties by remedial agents. A common principle is, therefore, concerned throughout. All the diversified results, whether physical, or vital, are directly dependent upon the existing condition of those properties. That condition is ascertained, in all its mutations, by the resulting phenomena.

626, b. Upon this ground, also, as upon that of the more internal economy, may be utterly exploded all the chemical and physical hypotheses of life and disease; since, were any of those doctrines founded in truth, the action of external causes should be directly upon the composition and structure. And so should the blood itself upon the sanguiferous system, urine upon the bladder, bile upon the intes-

tine, &c.

The moment we begin the study of effects as manifested by living beings, whether induced by internal or external causes, or those which arise from the action of living beings upon outward objects, we find ourselves surrounded by an endless variety of phenomena which denote the existence of a formative principle, upon which all the impressions are made, and which is the primary cause of all that are made upon external bodies,—which moves the body from one place to another, exerts all the changes that are effected in food, elaborates that, and that only, from the universal mass which is suitable for the formation of blood, which governs all the processes of organization, which is susceptible of alterations in its condition in consequence of the action upon it of many external objects, which is liable to analogous influences, healthy and morbid, from the operations of the mind and its passions, and which possesses an inherent tendency to return from a morbid to its natural state, the essential cause of preservation. Surrender these doctrines, and all our reasoning about organic beings, all our physiological and medical philosophy, would be a mere jargon of words. Hence it may be always seen, that those philosophers who deny the existence of a principle of life, or substitute the chemical forces, are driven to the necessity of speaking and writing as if allowing its full operation the moment they concern themselves about the phenomena of life. They must have, and they know it, a peculiar cause for effects so peculiar as those of organic beings.

627. In my examination of the constitution of the different tissues,

and of the properties and functions of life, the topics embraced within the present division of Physiology came, unavoidably, under analysis; and have been variously reproduced when investigating the laws of vital habit, the influences of age, temperament, climate, &c.

But little, therefore, remains to be added.

628. In regarding our relations to external objects we should carefully discriminate between irritability and sensibility, the two properties through which the relations are established; the former connecting organic life, the latter animal life, with the external world (§ 188, &c., 194, &c.). Vegetables, therefore, hold their connection through irritability alone; so that their organization is intimately associated with outward objects. The connecting anatomical structure in the organic life of animals consists of the alimentary canal, the lungs, and the skin; in plants, of the radicles and leaves (§ 268, &c.).

630, a. In organic life, as has been already seen, agents of all kinds operate through the medium of irritability (§ 188). Their effect depends upon the degree, and the kind of irritability, and upon the kind, energy, and quantity of the agents (§ 133, &c.). Owing to changes in the degree of irritability the same stimulus or sedative, and in the same quantity, does not always produce the same amount of effect. It will be more, or less, on one day than on another, even at one hour than another. This is constantly exemplified in the natural states of the body, but distinctly in disease, when irritability is also modified in kind as well as in degree. The law is of great importance in medicine, and is subject to many contingent influences, both in health and disease, especially that of vital habit. These influences involve some of the most difficult and delicate considerations in the practice of medicine, and more so from nervous complications.

630, b. Again, the alterations of irritability in morbid states, whether in degree or kind, will depend upon the virtues of the morbific agent, and upon the natural modification of the vital properties in any particular part. This combined condition, and according to its nature, requires particular adaptations of remedies, whose operation, also, will be in conformity with their own virtues, and with the natural and acquired conditions of the organic properties (§ 150, &c.). The principle is, also, equally true of all diseases in their develop-

ment of sympathetic affections.

630, c. From what has been said of the natural modifications of the vital properties in different parts, and of the specific relation of natural and remedial agents to those various conditions, it is obvious that the same morbific agent will affect one organ more or less differently from what it will another part (§ 133, &c.). Cantharides will not offend the stomach, but will excite inflammation of the bladder, and of no other part, in its proper therapeutical doses. And just so, though less remarkably, of the ordinary causes of disease. Cold and dampness constantly excite inflammation of the mucous coat of the nose, trachea, and lungs, while they far more rarely affect other parts. One poison strikes at the brain, another at the liver, and another at the skin, though their primary action may be often exerted upon the stomach. Other directions, however, may be given to each of these morbific causes when they are brought to act upon parts which are already diverted from their natural states, and will be liable to other variations from the numerous accidental influences by which every

individual is surrounded. It is these fluctuating influences which render measles, scarlet fever, the intermittent and yellow fevers, typhus, &c., more malignant at one time than at another, or more violent in one person than another. The same law obtains even in respect to idiosyncrasy, as in those subjects who are not affected by the poison of the rhus, &c. (§ 585, b). The differences result mainly from different modifications of irritability, and corresponding influences of various causes, not from "absorption and elective affinity."

630, d. As all morbific agents differ in their kind, so are the effects of all more or less different from each other. Each one, or according to their combined influences, other circumstances being equal, affects the organic states in one uniform way; and this is as true of the malaria which generate typhus and yellow fever, the plague, &c., as of the virus of small-pox, measles, hydrophobia, &c. The differences in results will, of course, be most strongly pronounced when the mor-

bific causes differ most from each other.

630, e. Many important practical considerations grow out of the principles involved in this section (§ 630), and which will come up for general remark under the remote causes of disease (§ 644, &c.). As an illustration, in greater detail, of a single element of this complex subject, let us now analyze the compounded influences which impart to measles, scarlatina, &c., their epidemic character, and their greater complexities when thus distinguished than in their sporadic form; and it will be seen, also, that the same principles are of extensive application to individual cases of all forms of disease, whatever be the nature of the compounded causes. Take, in the first place, epidemic fevers, epidemic dysentery, epidemic bilious pneumonia, &c. Here the causes may be mainly some special miasmata of intensely morbific properties, though more or less aided by the use of stimulants and stimulating food, &c., operating as predisposing causes subordinate to the miasmatic or essential cause (§ 648 c, 650-659, 662-663, 666, 870 aa). Coming to the contagious diseases, each malady has a more clearly defined predisposing cause, which is always generated by the special morbid states of these diseases respectively (§ 653). But in these affections when occurring epidemically, and sometimes in their sporadic forms, the miasmata that are indispensable to fevers contribute their malign influences in rendering the system more susceptible to the morbific effects of the contagious principle, increase the intensity of its operation, and lay the foundation of those local congestions of the abdominal organs which are attendant on epidemic fever, epidemic bilious pneumonia, &c. (§ 961-970, 1002-1005), just as stimulants and stimulating food operate in these miasmatic diseases. The same philosophy is applicable to the malignant cholera, which has for its indispensable cause some specific atmospheric virus, but often greatly promoted in its morbific effects by the predisposing causes of miasmatic fevers, and which concur in instituting the local congestions that are incident to those fevers (§ 654 a). The principle is the same, also, with those diseases where a predisposition to some specific form is impressed upon the constitution, as in scrofula, rheumatism, lues, &c. (§ 72-73, 75-79), and which modifies, or is modified by, the miasmatic influences that generate fevers (\$ 652 b, 660-662, 858). Superficial diseases, such as "putrid sore throat," erysipelas, &c., often spring from profound abdominal congestions, and are apt to be fatally mistaken for simply local affections (§ 689 l, 961 a, 970 c).—Note Oo p. 1141.

SEVENTH DIVISION OF PHYSIOLOGY.

DEATH.

631. Organic beings die; nothing else. What is it, then, that dies; and why, in consequence, do living beings return to the mineral kingdom? The functions, it is answered by many philosophers. But the functions are merely results. It is their causes, then, that perish. And what are the causes? The chemical philosophers answer, the forces which are capable of so many results in the inorganic world,the chemical forces. But the facts contradict that philosophy; for no sooner is the organic being dead, than we witness an exactly opposite series of results as the effects of chemical changes. We witness, I say, a demonstration of chemical results beyond any other example in the natural world, and it is then only that we witness them at all. The causes which are withdrawn must have been as peculiar as the universal phenomena that have disappeared, and as opposite to those chemical forces which take possession as their power of resisting them during life is unquestionable. These causes have been called the vital properties, which, like the powers or properties of the mind, are elements of one principle, which is known by the name of the vital principle. It is the extinction of this substantive principle which essentially constitutes death, as its existence essentially constitutes life. Those who deny its existence are generally, also, materialists in respect to the soul, if they be not chargeable with a greater vice.

632, a. The tendency to death, in man alone, having been introduced since his creation, the properties of life must have undergone some miraculous change. Man was created imperishable. By sin came man's death, by perseverance in sin, a farther abbreviation of life. We must admit this doctrine of Holy Writ, and apply it philosophically. We may not reason as to the Order of Providence, had the material man been immortal. Doubtless, ample "room" would have been provided for his indefinite multiplication, at least in the ultimate

abode of the translated Prophet.

632, b. But, assuming that life has been shortened from a thousand years to "three-score and ten" by the agency of physical causes, there must have been a miraculous change in the condition of the inorganic world, since it has been without change, in its relations to disease, up to the earliest records; but the very face of the earth assures us that there has been neither a natural nor a supernatural change in the condition of matter, or in the laws of inorganic nature. We are therefore compelled to take the Revelation of Heaven as it stands; or, in denying one part, to deny, also, the longevity of primeval man; which will obliterate all common ground between the disputants.—Notes C p. 1113, Pr p. 1142, Qq p. 1145.

633. Life does not generally reach what may be called its natural termination. We have already seen that its natural extinction is the work of its own progressive movements; that it is the result of the same creative operations that developed the ovum into the new-born offspring,—that continued the same process through the various stages of life up to the time of full maturity,—that still went on with the

work of superaddition, till at last, by the progressive condensation of organs, by clogging the sanguiferous system with interstitial deposits of bony matter, &c., it loses its control over its own instruments of action, and fails for want of means to carry on its productive operations. It is not, therefore, from any natural failure of the properties of life, or any "wearing out of the machinery," as is commonly supposed, that life ultimately becomes extinct, but from the prolongation of that process by which it laid the substratum for those active operations, which, when once begun, must be continued in uninterrupted progress along with the original creative function (§ 63–82, 123, 170 c, 175 b, 176, 237, 584). This ultimate effect, as well, also, as the exposure of life to the influence of morbific causes, is a striking exemplification of the Order of Providence in carrying out His final purposes in the natural world, where the general plan has been miracu-

lously diverted from its original design (§ 632, b).

634. The principal elements in the production of death may be found in the modes by which it may be suddenly effected. 1st. By the failure of the circulation, as in syncope. 2d. By the failure of respiration. 3d. By sudden and pernicious determinations of the nervous power upon the circulatory and other important organs. 4th. By the same determination of the nervous power upon the organic properties of the brain, as seen in instant death from apoplexy, anger, joy, surgical operations, blows on the stomach, &c., though, in these cases, there is also a pernicious nervous influence propagated to the heart, &c. (§ 230, 510, 511). Death from syncope is immediately owing to the failure of the heart to supply other parts with blood; though the nervous power is especially instrumental in prostrating the organs of circulation (§ 940-942, 947-949). Death from abolition of the respiratory function is owing especially to a consequent failure of the decarbonization of the blood. It is remarkable how speedily a loss of consciousness, and, of course, of all sensation, is sustained by the suspension of this function; and it may be of interest to some to know the facts as lately experienced in my own person. Being precipitated into a stream of water by the upsetting of a stage (my head through the window of the carriage), and perfectly conscious when first beneath the water, the reflections which occupied my mind could not have continued one minute. There remains the most distinct recollection of that brief period. The subsequent details, till consciousness was restored may not be without an interest. My momentary efforts at extrication were defeated by the weight of the passengers, and I continued to occupy the foregoing position till nine of them, and mostly females, could be lifted through the uppermost door, and while the carriage, heavily laden with baggage, could be rolled over. This process consumed at least some seven or eight minutes, and three or four more had elapsed after my extrication before signs of reanimation began to take place.* A large assemblage of farmers from the neighboring fields were standing around, when the first moment of consciousness was announced by a noise as of distant speakers, and a simultaneous view of the spectators. Vision was at once perfect; but the sounds advanced progressively nearer and nearer, and within a quarter of a minute had identified themselves with their proper sources; when, also, consciousness was completely re-established. It may be also worth saying, that only a very slight uneasiness attended the suffocation.

^{*} I have been since informed that the interval was more than twenty minutes. Nothing was done toward reanimation.

635. Nothing extinguishes life more immediately than a destruction of all the functions of the brain, whether by a direct injury of the organ, or by an abolition of the circulation. The effect is nearly as great when interrupting the respiratory process by dividing the medulla oblongata. But in this case the influences are different from such as obtain in diseases of the brain, or in injuries done to that organ. If sufficient to embarrass or to suspend respiration, the nervous power is determined with a pernicious effect upon all the organic viscera; but very variously, according to the nature of the injury or of the disease (§ 478-482, 510, 634, 948). A simple removal of the brain and spinal cord occasions death not only by suspending respiration, but by interrupting their influence upon the great organs of life; which must be also true within greater limits of the division below the medulla oblongata. In the former case, as we have seen, no pernicious influence of the nervous power is determined upon the organic viscera; in the latter, a direct violence being inflicted upon the spinal cord, a destructive effect is propagated upon the organic properties, which reaches to the brain itself (§ 129, 455, 456, $476\frac{1}{2}h$, 478, 479, 489, 507, 1032 d, 1037).

636. Death from disease generally depends upon complicated causes, and upon profound affections of more organs than one. In a general sense, also, the particular mode of death will depend upon the organs diseased, upon the violence and kind of affection, and upon

the particular condition of other parts.

637. It is rare that absolute death takes place at once in all parts. Evidences of this are seen in the peristaltic movements, in the contraction of the voluntary muscles, in the discharge of the arterial blood into the venous system, in the occasional exaltation of heat, &c., after apparent death (\S 447, d). We have seen, also, how remarkably the heart may be roused into action long after its pulsations have ceased (§ 262, 498 e, 516 d, no. 7), continuing, in some animals, to pulsate with a "rustling noise for ten hours after being hung up to dry" (Med. and Physiolog. Comm., vol. i., p. 17). In other instances, the heart has been "often seen to raise a weight of twenty pounds," soon after apparent death; and Lord Bacon states that he has seen the heart of a criminal, when the organ was thrown into a fire, leap up one foot and a half, and to continue these movements, with a gradual decrease, for the space of seven or eight minutes (§ 188, 233, $264, 265, 475\frac{1}{2}, 498 e, 647\frac{1}{2}$). In my work on the Cholera Asphyxia of New York, 1832, I have spoken of contractions of the voluntary muscles which continued in progress, drawing up the legs, &c., for an hour and a half after apparent death (p. 141). These contractions took place without the application of any exciting cause, apparently like the movements of the extirpated heart and intestine (\$ 262, 476½ c, 490, 498 e); but the latter are due to the stimulus of the air or other physical causes. There remains, therefore, no other conceivable exciting cause of the contractions than the stimulus of the nervous power arising from influences incident to the radical change in the organic constitution, analogous to that development which is attendant on syncope, and which in this case, besides its powerful demonstration upon organic actions, often induces spasm of the voluntary muscles (§ 948). The analogies in this respect, and such as are represented in section 500, are strongly in favor of reflex nervous action, while the corresponding action of the extirpated heart and intestine may seem to be opposed to it. The analysis, also, of sympathy which I have made in preceding sections (500, &c.) shows a special difference in the motive constitution of the organic viscera and of the voluntary muscles, and in the relative agency of the nervous power as it respects their motions. In the former case this power is particularly a modifying agent in organic actions; in the latter it is simply an exciting cause (§ 188, 205, 215, 222, &c., 258, 500, 524 d, no. 7, 891½ g, k, 893½).

If the foregoing construction be true, then the muscular contractions which follow, after apparent death, from blows upon the limbs, are equally due to the development and action of the nervous power (§ 516 d, nos. 8, 9); and the whole conclusion is farther strengthened by the involuntary movements of decapitated animals, and by the muscular contractions which are effected by the stimulus of galvanism, both in life and apparent death, and especially when consequent on pricking the skin after removal of the head. The latter case, indeed, is exactly analogous to motions produced in the limbs of the human subject by mechanical violence; since in the case of the decapitated animal there is no direct irritation of the muscles, and, therefore, no possible mode of propagating the impression upon the skin to the muscles, excepting by reflex nervous action. All this, too, shows us that, whatever differences may exist between the vital constitution of man and animals, and among animals, they are essentially constituted alike, subject to the same fundamental laws, and having only modifications ingrafted upon them.—Note A p. 1111.

It may be thought that all this is a useless refinement in philosophy. But such is not my opinion; nor have I any doubt that better minds will carry out these suggestions to more important developments in the philosophy of life. Even in death itself much may be gained that will be useful in physiology; and if we follow the organic being till he is resolved into elementary substances, we shall gather something at every stage of the process that will contribute light to organic science, and yield an interest to the study of putrefaction (§

54 a, 56, 62 e).

SUMMARY CONCLUSION OF PHYSIOLOGY.

638. From what has been hitherto said, it appears that medicine, in all its branches, is a perfect whole, bound together by intimate relations and dependences, nowhere contradictory, but all in unison, and irresistibly flowing from one great system of UNITY OF DESIGN, which is the grand characteristic. The foundation is laid in the Principle of Life, and its various attributes. The demonstrations of that principle, and of those attributes, begin with the elements of organic beings, their number, the modes in which they are united, &c.; and the sameness of the principle throughout, and the coincidences in its laws, are attested by every fact in physiology and medical philosophy.

By recurring to the demonstrations already set forth, it will be seen that my fundamental ground is clearly established; for, whether it be the elements of organic beings which are combined in peculiar numbers, proportions, and modes, and forever in one peculiar and exact manner in every distinct part of every organic being, and which are maintained in combination against the adversities of disease, and against those chemical agencies which may produce their almost instant dissolution when the vital chain is severed; and whether we consider, also, the remarkable nature of those elements, and that in the animal kingdom, especially, nitrogen gas abounds in the various tissues, notwithstanding the entire kingdom is far more liable, than the vegetable, to chemical decomposition after death; or, whether we pause at the threshold of life, and consider all the unvarying facts attendant on the development of the ovum, how one part after another springs into existence in a never-deviating, foreordained manner, and as each part may be necessary to the next succeeding, how the same exact process of formation, and no other, is continued till the being becomes again a subject for the mineral kingdom; how the semen, also, is a type of all the various subsequent agents of life; how we may here detect the nascent causes of transmitted disease, operating in conformity with those which play their part in the external world; how mind itself is impressed upon the embryo, and how the intellectual peculiarities of either parent may be ingrafted upon the offspring, as are their physical traits, their temperament, their constitution, their very manners,—where, I say, all is uniformity in the grand movement of organization, and nothing but coincidences in the fluctuations that may arise from preternatural causes, and always the same according to the precise nature of those causes; or, if we follow the immature being to its state of maturity, and observe that the progress of development is always the same, under equal circumstances, at every stage of its progress, whether in the animal or the plant, and notice, also, the coincidences which obtain between the two organic kingdoms, as in the changes of tissues, in the variations of products, up to the consummation of the whole in that perfect state which is characterized by the development of the generative organs, the flower, the ovum, the seed, and the mutual office of sexual intercourse; or, whether it be a corresponding exact organization and vital endowment of every part of every organic being, yet different in every organ, and often so in different parts of one and the same continuous tissue as it traverses

different parts of the compound organism; or, whether we regard the products of each organ, or of each tissue, or of the several parts of a continuous tissue, respectively, and observe that they are forever the same in the same animal or plant, under equal circumstances, yet different in every part, and more or less different from each other in every species, whatever the similitude, or consider that the same products are forever modified in health and in disease in one exact manner, under any given modifying influences, whether natural, morbific, or remedial; or, whether we interrogate the nature of the relations by which external or internal causes divert the phenomena from their natural states, and observe that the results depend upon the exact original and acquired nature of the part and the nature of the influences, and that they are in perfect harmony with such as emanate from the natural stimuli of life; or, whether we consider how the manifestations of disease denote, like those which emanate from the natural stimuli of life, an established difference in the closely-allied constitution of the same or different tissues, and different parts of a continuous tissue, as in the inflammatory affections of various parts of the mucous, or the serous tissues, and the more remarkable peculiarities attending the inflammations of the lining membrane of the veins. -prostrating the circulation and giving to fever its malignancy; or, whether it be a small current of air impinging upon the neck, which will suddenly induce an attack of catarrh, or of pneumonia, or of rheumatism, when no such effect may follow an equal exposure of any other part of the surface, or even of the entire skin for an equal time; or whether, in a remedial aspect, leeches, or a warm bath applied to the feet, may restore menstruation when the same applications to other parts might be insufficient, or other analogous phenomena which abound in the history of morbific and remedial agents; or, if we consider the philosophy which concerns the first act of inspiration as generated by the contact of air with the surface of the body, and that it is exactly the same as that which is relative to the first inspiration in syncope when cold water or cold air are applied to the face, or stimulants to the Schneiderian membrane, and even the same when the mucous tissue of the lungs becomes the point of departure,-the same, too, which concerns all those modifications of respiration which are known as coughing, laughing, crying, sneezing, hiccough,—the same as obtains when light, impinging upon the retina, produces either a contraction of the iris or a paroxysm of sneezing,—the same as when a leaf of tobacco applied to the sole of the foot may disturb every function of the body,-the same when cathartics, or emetics, or alteratives, &c., may send their influences abroad through the medium of the gastro-intestinal mucous membrane,—the same when shame mounts to the face, or fear expels the blood from the surface, or covers it with moisture, or stimulates both kidneys and bladder, or as anger convulses the heart and braces up the animal muscles,-the same, in principle, whether one or the other be applied in a physiological, pathological, or therapeutical sense; or, whether we regard the organism as a whole, and consider how all parts concur in harmony together; how numerous parts are supplied by natural stimuli, consisting of blood or of products from it, which conspire together in maintaining the good of the whole, but either of which would be offensive to other parts, and disturb the harmony of the whole; or how the nervous

power sheds its regulating influence upon all parts of the animal mechanism, and how, through that same power, from its natural susceptibility to the existing healthy state of every organ, both external and internal causes may lay the foundation of disease, or effect its removal, or occasion the most violent commotions, or extinguish life in a moment; or, whether we consider that the same relative facts prevail in respect to the vital signs that distinguish the physical products, and that they go hand in hand together, under the same established or contingent influences, natural, morbific, or remedial; or, whether we scrutinize the coincidences between the facts that are relative to the changes that happen at the different eras of life, and to gestation, lactation, &c., and such as are brought about by morbific and remedial agents, and consider that the latter are a necessary consequence of the natural mutability of the fundamental constitution from which the former emanate; and that those which are natural are an exact type of the influences and their mode of production when morbific or remedial agents operate upon distant parts by impressions exerted upon the stomach or skin, or when disease of one organ gives rise to disease in another; or, whether we regard the corresponding facts which are relative to vital habit, or those which result from the influences of climate, &c., and which bestow the radical modifications that form the peculiarities of temperament, &c., and see, also, that all these variations are produced by causes that operate through the same fundamental constitution; or, whether our hygienic and therapeutical treatment may be greatly regulated by each of the foregoing conditions, whether natural or acquired; or, whether it be the peculiarities of idiosyncrasy that render certain ordinary articles of food morbific to certain individuals, or the analogous constitution of marine and terrestrial plants which demands for the former the briny waters of the ocean, while they are fatal to the latter; or, whether, in like way, the mere approach within ten feet of the poison rhus will produce a violent erysipelatous imflammation over the whole surface of one person, when even the handling the plant will never affect another; or, whether the rolling of a few blue pills with the fingers will establish salivation, and affect the adult constitution of some, while a pound of calomel taken by the stomach will not affect others in a similar manner, and rarely at the early stages of life; or, whether it be bloodletting, or the mercurial or the antimonial alteratives, that are often baffled by the precise modifications of the specific forms of active inflammation, while they readily subdue the common form and many specific chronic inflammations, and whose differences in results denote the modifying influences of the remote causes of closely analogous affections; or, whether mercurial agents be strictly morbific in their action upon the salivary glands, while they are simultaneously and powerfully curative of hepatic and other diseases; or, whether a mercurial cathartic will induce salivation if the susceptibility of the system be increased by the associate use of other cathartics or by loss of blood, when, per se, no such effect may be produced; or, whether the same effect follow the mitigation of fever, when no extent of the remedy may reach the constitution in high grades of febrile action; or, whether the bite of the mad dog will produce hydrophobia in all mammalia, while the disease cannot be imparted by any other than the canine and feline tribes; or, whether the poison of the rat-

tle-snake, or of the wourari tree, or numerous other poisous which are certainly and rapidly fatal when inserted beneath the skin, be perfectly innoxious when taken into the stomach or applied to the surface of the brain; or, whether it be the virus of the small-pox, of measles, &c., that effects certain modifications of the vital states relative to each particular agent, and to no other, that forever protect the system, in a general sense, against a second attack; or, whether it be the cow alone, as with other animals in respect to the virus of hydrophobia, that can so modify the variolous poison as to generate in man the equally protective vaccine disease; or, whether the suscep ibility sometimes remain so as to give rise to another modification while the varioloid, in its mildest state, but not the vaccine, will generate, by contagion, in the unprotected, the most virulent form of the original disease; or, whether it be the analogous miasmata that only slowly extinguish the susceptibility to their morbific effects after repeated attacks of the particular forms of fever which they are, respectively, capable of producing, or, if the subject thus acclimated remove to another region, his original susceptibility may return,—being analogous, also, to those physical agencies which establish the temperaments, and which change from one to another as the old influences may cease, and new ones operate, while analogies, in these respects, are also supplied by the variolous and vaccine diseases; or, whether it be bloodletting, or an emetic, or a cathartic, that produce their alterative effects with a rapidity proportioned to the rapidity in which their sensible operation goes on; or, whether it be the alterative in small doses, and in its abstract sense, that slowly establishes analogous changes in the morbid states; or, whether an alterative, as antimony, for example, must be generally increased in its successive doses to keep up the effect of the first dose, or, if there be, in respect to an timony, a suspension of the remedy for at least twelve hours, we must then go back to the original smaller quantity to avoid an exces sive effect; or, whether, on the other hand, other alteratives, like mercury, or foxglove, or cantharides, or arsenic, or quinine, or ipecacuanha, will manifest no sign of their influence for several successive doses, but will, at last, without any increase of the dose, suddenly display the full effect of their virtues; or, whether by associating ipecacuanha with the sulphate of zinc, the latter will so exalt the susceptibility of the stomach that the two agents, otherwise une qual in time, will simultaneously co-operate in their emetic effects or whether, in the same way, a diffusible stimulant, associated with a permanent tonic, will quicken greatly the action of the latter; or whether, in like manner, and like the virus of small-pox, of measles, &c., or like the miasmata, it be opium, or hyoscyamus, or digitalis, or mercury, &c., that reduce or increase the susceptibility of the stomach and of the general system in relation to the virtues of each agent, respectively, but to those of no other; or, whether we consider other examples of vital habit, and observe how pungent stimuli cease to annoy the nose, the mouth, the stomach, &c., but only so in relation to each of the agents, respectively, or how tobacco, which is morbific in most diseases, and originally offensive to all, finally becomes the most universal luxury of man; or whether we consider the manner in which the alteratives, in there small and oft-repeated doses, maintain their influence, and extend their silent

invasions upon disease, or how emetics, or cathartics, continue to propagate their curative effects after their complete expulsion from the body, and see that the principle is disclosed by the natural phenomenon of the permanent contraction of the sphincter muscles, which, although the urine or the contents of the rectum be evacuated, are maintained in equal contraction by the irritation which remains upon the mucous tissue, and through which the nervous power is uninterruptedly reflected upon the sphincter muscles; or whether we regard the coincidence between respiration, spasmodic affections, and the voluntary movements of the respiratory, or of other muscles, and observe that each is alike due to the propagation of the nervous power upon those muscles; or whether we contemplate the same vital agent in its production or removal of disease, and in its absolute mode of operation, and see that the changes which are thus effected consist in some alteration of the natural or morbid states, and according to the nature of the remote cause, whether it be positive, like mercury, or negative, like cold, or immaterial, like the mind and its passions, and according, also, to the special exercise of one mental power or another, or the operation of one passion or another, and thus proving the susceptibility of the nervous power to various modifications that coincide with the virtues of the remote cause, and a coincidence, in this respect, with the changes which are perpetually exhibited in the organic vital conditions, and which are even brought about by the nervous power itself; or, whether we realize the foundation of these last phenomena in the naturally exquisite susceptibility of the nervous power to various influences, that it may constantly operate as a regulator of the rhythmic movements of all parts, and through a law of the nervous system by which all parts are exquisitely sensitive to the condition of each other, and through which all remote morbific and remedial influences are exerted; or whether, in like way, inflammations are varied in their character by contused, and punctured, and incised wounds, or more greatly so by all animal and vegetable poisons, whether morbid or natural, and mostly so according to the special nature of the remote causes, respectively, or, if subordinate influences diversify the effects of many principal causes, there be others which control all other influences, as in small-pox, measles, scarlatina, &c.; or whether in fever, as in inflammation, there be analogous varieties, corresponding, in like manner, with the special virtues of each cause, while the fundamental pathology is of one common nature in all the varieties of inflammation, and of another common nature in all fevers; or whether an ephemera be the type of the intermittent, the remittent, and continued fevers, and of their several modifications, and consider how the paroxysms of the intermittent commonly observe established intervals of twenty-four, forty-eight, and seventy-two hours, or, if the usual time be anticipated or delayed, the paroxysms are then apt to go on with the particular irregularity with which they began, or when, by regular anticipations of the period of each last preceding paroxysm they approach the night, one paroxysm is often lost; or whether we look at the effects of all our best and most universally remedial agents, as bloodletting, mercury, antimonials, cathartics, &c., and see that they are strictly morbific to the healthy system, in their remedial doses, and that, therefore, they are at least equally so in their action upon diseased organs, yet contributing to their cure; and while, also, we

know that neither such nor other agents can, of themselves, transmute the morbid organic changes to those conditions which are natural to the being, we yet discern the reasons of their favorable effects in the spontaneous and successful efforts of unaided nature, and in those speedy recoveries from morbid states that are induced in the healthy system by remedial agents, in their remedial doses, and thus infer that remedies only contribute to the cure of all diseases by instituting morbid changes that are more conducive to the naturally recuperative process; or, whether the cure of intermittents be effected by bark, or arsenic, or cobweb, or opium, or an emetic, or bloodletting, or abstinence, or by an emotion of the mind, &c.; or whether it be stimulants or sedatives, bark or bloodletting, conjointly or separately, that may subdue many inflammations, acute or chronic, and thus, also, prove the near identity of the pathological state in all the varieties, and that nature recognizes no such opposite conditions as active and passive inflammation; or whether it be the abrupt removal of pertussis by an hour's exposure to the open air where all other means had failed, or the improvement of an ulcerated limb by the same temporary influence; or whether ice, or ipecacuanha, or common salt, or opium, or bloodletting, or the sulphates of zinc, and of copper, or catechu, or kino, &c., will alike arrest capillary hemorrhage or redundant secretions, by modifying the action of the capillary vessels; or whether loss of blood, and tartarized antimony, or a dash of cold water upon the surface of the body, or even a warm bath, be far better "refrigerants" than pounds of ice, or of lemonade, taken into the stomach; or whether, among the "sudorifics," the drinking of hot water, of mint-teas, &c., will excite a more immediate and more profuse perspiration than tartarized antimony, or ipecacuanha, &c., and the former exert no other apparent effect, while the latter may be profoundly curative or morbific, or bloodletting surpass the whole in all these respects; or whether it be the "sialogogue," like horse-radish, which only exerts an effect on the salivary glands through a continuous irritation along the salivary ducts, or mercury, which induces salivation only by constitutional influences; or, whether we turn our attention to other corresponding laws, and to other analogous coincidences, and consider, for example, how all but chyme is prevented from passing the pyloric orifice, how all but the air is excluded from the lungs, how all but chyle from the lacteals, how all but white blood from the serous vessels of the arterial system, notwithstanding the far greater diameters of some than those of the red globules, and yet that when the irritability of one is morbidly affected, as in indigestion, solid food will pass out of the stomach; or of another, as when certain morbid impressions are made upon the lacteals, the deleterious agents may obtain a sparing admission; or of another, as in inflammation, the red globules are allowed to pass freely in; or, if we glance at those more astonishing phenomena which attend the generation of animal heat, and observe that all non-hibernating mammalia maintain one uniform temperature, under all circumstances of food, clothing, &c., whether at the poles or at the equator, yet each species, respectively, possessing a temperature of its own, and that the very giant of the mammiferous tribe, in the midst of everlasting icebergs, obeys this law of uniform and exalted heat,exalted not less than four degrees above that of man; or turn our admiring contemplation to the few exceptions that occur in the hi-

pernating group, and see how that temperature, which is equally uniform under all torrid and temperate degrees of the circumambient air, sinks down as the thermometer descends from 40° F. till the animal scale reaches nearly the freezing point, and then rises, with a bound, to its original exalted standard, while the mercury goes on to the point of zero; or, if we drop from this gradation in analogy, to the cold-blooded race, and observe how they obey the physical law of an interchange of caloric with the surrounding medium, yet within the limitation of a specific and independent power of maintaining a counteracting influence that preserves them at a few degrees of heat above the lowest of the external medium which may be endured,eating, digesting, and performing, too, the same organic functious as the mammalia; or, if we consider, also, the same peculiarities in the living egg, and their absence where its incubating property is extinct; or, if we turn ourselves to the vicissitudes of temperature which attend the phenomena of disease, and remark how they correspond with all the admitted vital changes,—rising, in one case, to a degree of intensity where there is almost a total privation of food, and an extensive destruction of the lungs, or sinking, in another, to an almost icy coldness, where the subject is plethoric and the stomach is crowded with food and alcoholic stimulants; or whether, also, we regard the same principle in its natural state, as seen in the process attending the reproduction of the stag's horn, or in that of lactation, and consider that here is the fundamental element implanted in the constitution for great and wise purposes, and that every other consideration points us directly to the natural constitution itself for an interpretation of every phenomenon in the history of animal temperature, and deduces a coincidence between these phenomena and those of the organic processes, under every aspect of stability, individuality, and of change; or whether it be a thousand other different, but analogous considerations, relative to the influences of foreign, natural, morbific, or remedial agents upon man or other organic beings; or whether we again look to the mind and its passions, and see the long exercise of judgment impairing digestion, while imagination comes in as a speedy restorative; or whether it be anger or joy, like a blow on the stomach, or like the shock of a surgical operation, that strike us dead in a moment, or grief that does but slowly undermine, or hope that throws its balmy influence over every disease, by whatever cause produced ;whether, I say, it be one or the other of the considerations now mentioned, or thousands of thousands of similar import, which crowd the history of living objects, each and all are in harmony with each other, and concur together in one universal demonstration of the peculiar constitution of animated beings as distinguished from the inorganic kingdom, and declare their essential dependence upon one principle, namely, a VITAL PRINCIPLE, of various elements or properties, whose definite character in their natural conditions, and whose instability or liability to permanent and temporary modifications and changes, and whose disposition to return from such as are only temporary to their original state, lie at the foundation of all the phenomena, will explain every phenomenon, and whose unity as a whole is supported by every phenomenon of organic beings. This consideration, therefore, assures us that we have already compassed the general philosophy of life, of disease, and of medicine; and we contemplate with admiration the simplicity, yet complexity, of the principles, the stupendous whole, as it swells from the comparatively simple phenomena of the development of the ovum, when the properties of life are exposed to no influences that shall affect their instable nature, till we have traversed the animal kingdom in all its exposures to those influences, and have witnessed the incalculable variety of change which the organic properties and functions sustain in consequence of those exposures, and observe that the whole immense system, all the variety, springs from the simple influences of external and internal causes upon the properties of life, and that slight changes in these properties, like the differences which prevail among the results of their natural modifications in different animals, and in different parts of a common or a continuous tissue, give rise to all the differences between health, disease, and convalescence; -in the contemplation of all these things, I say, we are employed in witnessing the most comprehensive and sublime system of Unity of Design, and enjoy the conviction that we are cultivating a science whose foundations are laid in the most Consummate Wisdom (§ 1085).—Note Rr p. 1145.

REVIEW OF THE LAWS OF REFLEX ACTION OF THE NERVOUS SYSTEM, AND AS APPLIED PATHOLOGICALLY AND THERAPEUTICALLY.

6381. A large space has been given to the consideration of the nervous system, especially to experimental observations upon it, for the purpose of developing the Laws of Reflex Nervous Action, or, as I have called them, also, for obvious advantages, Remote and Contiguous Sympathy, or, indifferently, Sympathy. All this inquiry has been made with a sole reference to the application of those laws to many important problems in *Physiology*, particularly nutrition, secretion, modifications of structural development, calorification, and circulation, and to erecting upon them a substantial and philosophical fabric of Pathology and Therapeutics, which still lies extensively before us, and for the purpose, also, of simultaneously accomplishing the overthrow of the chemical and physical doctrines now prevailing in all the departments of medicine. Although I am about to enter upon the specific application of the Laws of Reflex Action of the Nervous System to Pathology and Therapeutics, I have, nevertheless, been constantly employed in exemplifying the morbific and therapeutical aspects of those laws as founded upon their nat-An indispensable requisite for this application is a reaural conditions. sonable proof of the modification of the nervous power according to the nature of the cause, whether physical or moral, by which it is brought into preternatural operation, nor is there any other consistent or intelligible mode of interpreting the great range of pathological and therapeutical problems, and the multifarious displays of the passions in organic life, according to their individual nature. The whole of the Author's philosophy upon this vast subject is predicated of the well-established laws of reflex action of the nervous system, nor is he aware of any fact by which that philosophy is contradicted, while, besides the admitted premises, it is sustained by the whole history of morbific and remedial agents, and by the diseases which grow out of, and are maintained by, each other. It may be finally added, that, although the Author has shown that the passions, the will, cerebral diseases, and other causes acting directly upon the nervous centres, develop and project the nervous power without the intervention of sensitive nerves, he has also shown that the essential philosophy is the same as that which respects reflex nervous action (§ 453).

PATHOLOGY.

639, a. Having now laid a broad foundation for the superstructure of pathology and therapeutics, in the exposition of the properties, the functions, and the laws of organic beings in their natural states, and in contrasting the philosophy of the more difficult problems with those interpretations which have been borrowed from the phenomena of the inorganic world, that nothing may obstruct our way, and that whatever is true in any of the conflicting views may shine with greater lustre, I am thus prepared to go on with those lofty objects about which the healing art is immediately interested. I say, to go on; for in all my physiological inquiries I have endeavored to indicate their relations to the ultimate branches of medicine, and to approach these branches already prepared with a connected view of their dependence upon natural institutions. The complexities in physiology give rise to corresponding intricacies in pathology and therapeutics, and it has been therefore necessary to explore the ground-work in such various methods, and with such variety of illustration, as shall impart to pathology and therapeutics a consistency in principles, a ready interpretation of their endless problems, and give to the hand of art enlightened confidence and firmness in the right. I have designed that this right shall follow naturally and easily from the premises hitherto laid down, and if I have come short of that, then have I failed in fundamental requisites. No system in physiology can stand which is not true to Nature in her altered aspects; none that does not come to her interpretation under all the varied conditions and phenomena of disease; none whose elements conflict with each other (§ 516 d, no. 6, 524 a, 524 d). There must be clearness, individuality, harmony, demonstration. I claim not that I have accomplished all this. I do but say that I have attempted it, and with an earnest hope that the effort may not prove abortive. As much has been said, and much remains, which is original with myself, and generally relative to the most profound and important topics, and, as there has existed the necessity of exhibiting in a satisfactory manner those conflicting errors which have obtained such general ascendency, I have been impelled to all the amplitude of inquiry which may obtain either the acquiescence of the profession in the doctrines which I have taught, or their ready rejection (§ 1, 285, 1067).—See Rights of Authors, p. 912.

639, b. Pathology concerns the changes which the vital properties and functions undergo in disease, and the resulting changes in the vital and physical signs, and finally reaches to those lesions of organization that fall within the purview of morbid anatomy (§ 695,

&c.).

Pathology consists essentially, therefore, of those modified states of

the physiological conditions which constitute disease.

640. Such, also, are the relations between the natural physiological conditions and those diversions which make up disease that the latter often reflect the most important light upon the natural ones. The properties of life, in all their aspects, as well as their corresponding

functions, are not unfrequently best comprehended through the phenomena which distinguish their various departures from the normal standard (§ 198, 303\frac{3}{3}). Chemists, therefore, cannot be physiologists.

641. Pathology is divided into general and special. The first considers diseases in common; the second treats of the particular history of diseases. A distinction has been also made into medical and surgical pathology; but it is unfounded in nature, though it may be convenient in practice.

642, a. As all diseases have their remote causes, which often reflect much light upon pathological conditions, these should be embraced in

the department of pathology.

642, b. The vital properties are so susceptible in their nature that the good, as well as the evils of life, is constantly inflicting disease. Whatever is salubrious in due proportions becomes morbific in excess. The mildest nutriment in excessive quantities, or at unseasonable times,—an unrestrained indulgence of the passions,—inordinate exercise, &c., prove the instability of the vital powers. We are also surrounded by agents of noxious virtues, some of which we may avoid, but covet as luxuries,—while others, if we would avoid, are beyond our control (§ 150, 152).

643. We are therefore led to consider pathology under three prin-

cipal heads; namely,

I. Remote Causes of Disease.

II. Proximate or Pathological Causes.

III. Symptoms.

I. REMOTE CAUSES.

644. The remote causes of disease are the first in the series. By their deleterious action on the properties of life they give rise to those changes which constitute the proximate or pathological causes, or the essential conditions of disease (§ 188-192).

645, a. Remote causes are subdivided into predisposing and exci-

ting or occasional causes.

645, b. The predisposing causes are the most important; being indispensable to all idiopathic fevers, and to all specific forms of disease.

645, c. The exciting or occasional causes are such as develop an attack of disease after the predisposing have laid the foundation. The latter, therefore, may produce their full impression, and the subject escape an attack, unless afterward exposed to the exciting causes. The predisposing, however, often operate with such intensity as to prove exciting, also; as in small-pox, measles, hydrophobia, poisons, injuries, malaria, &c. (§ 559). But the mildness, or intensity, of many of these affections, as in the contagious diseases, may depend upon the antecedent operation of other modifying causes; whether of a predisposing or protective nature (§ 630 e).

Again, the exciting cause often consists of something which, under ordinary circumstances, may be perfectly inoffensive; such as a full meal, a few glasses of wine, privation of sleep, anxiety, grief. In such cases there has always been an antecedent predisposing cause in operation; but either of the foregoing may operate both as predis-

posing and exciting causes.

646, a. Remote causes are either internal or external.

646, b. The internal consist, for example, of the passions, laborious

study, retention of the fæces, hereditary predispositions, &c. (§ 75-80,

144, 561).

646, c. The external consist, 1st. Of such as are ordinarily salutary, but become morbific by their excessive or too frequent use, or when used at undue seasons, or when the body is disqualified for their use. 2d. Such agents as injure mechanically the structure of our bodies. 3d. The great class of truly morbific agents, which embraces a large variety in the several departments of nature, comprehending, even, a large proportion of the materia medica, when exceeding the therapeutical doses, or when employed in these doses under circumstances of health (§ 177, 191 b, 237-240, 524 d, 854 c-f, 893, 900, 901, 905).

647. Among the most important of the internal remote causes of disease are morbid conditions already formed. They may be either exciting or predisposing, or operate as conjoint causes. In the former case other causes have brought about the predisposition. They are

the great fountain of sympathetic developments.

 $647\frac{1}{2}$. The nervous influence, reflex or direct, is the immediate remote cause (predisposing or exciting), of nearly all disordered states beyond the seat of the direct action of other causes ($\frac{9}{222} - 233\frac{4}{2}$).

648, a. The predisposing causes are general and specific.

648, b. The general are such as may be in simultaneous operation upon many individuals, and are, then, mostly connected with the atmosphere, giving rise to influenza, and other catarrhal affections, &c. Of these there are commonly several in combined operation; though there is generally one more important than the rest, especially in acute forms of disease.

They consist, also, of all those causes which give rise to the various forms of *common* inflammation, and all other conditions of disease

which do not fall under the next subdivision.

648, c. The specific causes form a far more numerous class than the general. They consist of all the natural or healthy and morbid poisons, animal and vegetable, and the principal agents of the materia medica. Each of these will generally establish the predisposition by itself alone, and is generally the exciting as well as the predisposing cause. Among these causes must be ranked all those which generate idiopathic fever; and these being of vegetable origin must float in the atmosphere, and around the multitude. They are, therefore, the main causes of epidemics, properly so called (§ 650, 663). Such causes are generally aided in the development of disease by others which are simply exciting (§ 654, a).

648, d. The predisposing causes of sporadic diseases are apt to be

more numerous than those of epidemics.

649, a. Remote external causes do not produce their effects indiscriminately on all parts to which they are applied. Some are perfectly inert upon the skin, while others exert their principal effects upon this organ. And so of other parts. The surfaces upon which they operate are, 1st. The mucous tissue; 2d. The skin; 3d. The surface of wounds and abraded parts; 4th. By being forced into the vessels when wounds are made by instruments charged with poisons. It is in the last two ways alone that many of the most active poisons produce their effects; such as the hydrophobic viras, the poison of serpents, the poison of dissection-wounds, &c.

649, b. Some parts of a continuous mucous tissue are more suscep-

tible than other parts of the same tissue (§ 132-137). And so of the skin. A current of cold air, for example, striking the neck more readily produces catarrh than when impinging on any other part; while its direct action upon the healthy mucous tissue of the lungs is never deleterious (§ 136). Menstruation is most readily suppressed

by cold applied to the feet, &c.

The foregoing facts depend upon a principle of vast importance in every branch of medicine. Thus, in relation to the pulmonary intestinal mucous membrane, we learn from it, physiologically, that the generation of gastric juice, and the elaboration of carbon from the blood, are conducted by special vital processes, &c. (§ 135, 419), and this, with various other relative facts, such as the variety in effects of natural stimuli, goes to illustrate what is denoted by morbid phenomena of the special susceptibilities of different parts of a continuous tissue to the action of morbific causes, and how the same disease presents important varieties in the several parts; and, carrying these important considerations to therapeutics, we readily come to a distinct apprehension of the reason of the differences, local and constitutional, which spring from the action of the same remedy upon one part or another of that same tissue; as, for example, why tartarized antimony may relieve croup by its action upon the stomach, but may kill in the same case by an equal effect upon the intestine. And now, casting a glance at the universal body, we see the same law prevailing in other tissues, and among all parts which differ in organization. These combined circumstances open an immense field of philosophical and practical inquiry, and should forever employ the physician in a critical study of the therapeutical relations of the various articles of the materia medica to one part or another, in their local and sympathetic effects, and according to the precise pathological conditions of all the parts which are likely to feel the influence of the remedy, or as it may affect the more natural conditions of other parts, and, therefore, their favorable or unfavorable reflected sympathies (§ 129-152, 500, nn, $514 h, 638\frac{1}{2}$).

649, c. There are probably but few ordinary morbific agents which affect the skin in its sound state, though some may which are not suspected. Cold is one of the most remarkable. There are but a few of the active poisons of the materia medica that affect either this organ sensibly, or other organs sympathetically through it. Mercury, tartarized antimony, and cantharides, are among the strongest examples of the action of remedial agents upon the skin, and through that organ upon remote parts. But, while blue pill, and the blue mercurial ointment, which are demonstrably not absorbed, produce inflammation of the salivary glands, and affect the system at large, after their application to the skin, they exert no more manifest effect upon the skin itself than when a cold current of air gives rise to pneumonia or rheumatism (§ 657 a). And since the foregoing preparations of mercury are no more absorbed than the cold air, it is evident that their direct action, like that of cold, must be exerted through the cuticle upon the susceptible properties of the skin (§ 514 d, 826 c, 1059, 1088 b).

Cantharides and tartarized antimony, on the contrary, affect the skin sensibly, and in a direct manner, and other parts, as in the foregoing case, by sympathy. But, tartarized antimony applied to the skin will not induce nausea, nor affect the constitution at large, whatever its

morbid susceptibilities, but only certain parts in the vicinity of its application, and then only when those parts are preternaturally susceptible (§ 143). It then operates, like blisters, through contiguous sympathy (§ 497, 1088 b). And so equally of croton oil (§ 893 a, 905).

When, however, almost any article of the materia medica is taken into the stomach it produces an obvious impression upon that organ, or upon the intestines. Reflex nervous influences are then transmitted to other parts; and it is upon this great law in relation to the intestinal canal especially that the curative effects of remedies depend. A strong analogy is also thus supplied in proof of the primary action of many of the profoundly morbific agents upon the alimentary mucous tissue; since the positive remedial agents are as truly, though more transiently, morbific (§ 901). It may be one part or another of that tissue,—where it traverses the nose, or the mouth, or intestines, ac cording to the special virtues of the operating cause, and the natural or acquired modifications of the vital states in either part (§ 150, 649 b), just as one mental emotion or another will, through direct nervous action, strike at this part or at that of the foregoing tissue, or again descend upon other parts of the organ as it may fluctuate in its vital states; or, at other times, may aim at other organs (§ 227, 500). The mucous texture of the lungs is, also, doubtless, often the seat of morbific influences from external agents; though here we have no great range of analogies.

649, d. The reason why the skin is so little susceptible of the influence of morbific and remedial agents consists partly in the protection which is afforded by the cuticle; not, however, because of its supposed impervious nature which is inculcated by the mechanical philosophy, but that the cuticle is a mere shield to the very susceptible properties of the true skin. When, therefore, that guard is removed, numerous agents operate with great and rapid effect, and send their influences abroad with great power over the system. Hence, one of the obvious final causes of the cuticle.—See p. 930, § 1088 b.

650. Every distinct morbific agent (and every remedy), however allied to others, has its peculiar virtues, which produce, cateris paribus, a general corresponding modification of the vital properties and functions (§ 52). If two or more be united, chemically or mechanically, the compound is an agent of new virtues, and produces corresponding effects (§ 1882, d). This is the reason for combining remedial agents. Hence arise many varieties of inflammation, and of idiopathic fever; the differences being greater where the morbific causes differ most from each other, or, as two or more may operate (§ 766). This is rendered distinctly obvious by the specific character of those diseases which follow the application of morbid or healthy animal poisons in each of the cases, respectively. Thus, the poisons of smallpox, of measles, of scarlet fever, &c., always affect the vital condition in nearly one uniform way. From these distinct and strongly-marked affections we might safely reason to all other morbific agents; but, independently of this analogy, which rarely fails in relation to any organic laws, we have the same proof, though less remarkable, in respect to other affections. In the great family of idiopathic fevers, among which there are close resemblances, there is no rational doubt that each variety depends upon specifically different predisposing causes. It appears, also, to be well ascertained that these causes are of vegetable origin, and that the differences in their nature depend upon different combinations of their elementary principles, that take place during the decomposition of vegetable matter. This difference in decomposition, and the consequent generation of each peculiar poison, according to the new and exact modes in which the elements recombine, is owing to various chemical influences; such as peculiar states of the atmosphere as to heat, moisture, light, &c.; and also upon the kind of vegetable matter, its simplicity or variety, the nature of the soil, whether wet or dry, whether impregnated with fresh or salt water, or whether the vegetable matter be superficial or mixed with earth, &c. Certain climates, cities, &c., will generate varieties of fever, and of other diseases, which never happen in other places (§ 1068, b, note).

All the foregoing has its exact analogies in the natural agents of

life (§ 136).

651, a. The predisposing causes, nevertheless, give to disease no small part of its special character, while in each tissue, or part of a tissue, of any given organ, the exact pathology also depends on the

special vital constitution of that part (§ 132-152).

651, b. Age, sex, habits, &c., exert, also, certain influences upon the results of the remote causes of disease; and it is owing to analogous changes in the vital states that the usual effects of any morbific cause in ordinary constitutions may be variously modified in constitutions which possess natural or acquired peculiarities, &c. The influences left by former diseases, and whatever may have diverted the properties of life from their perfectly natural character, or have increased their susceptibility, will be conducive to the deleterious action of morbific causes, and of many of the ordinary stimuli of life, and may variously modify the results in the several cases, respectively. Hence there is scarcely a limit to the modifications of disease, while they may agree in the general outlines (§ 153–156, 163, 535–630).

652, a. By no circumstances, however, is the pathology of disease so greatly determined as by the predisposing causes; and this important result, therefore, will be more or less affected by the simplicity or the variety, and intensity, of the causes, as well as by their nature.

(§ 722).

652, b. But, there is not only one predisposing cause which is generally most important, and which mostly rules the pathology, but there are many morbific agents which are capable of so controlling all other influences as to determine certain uniform morbid conditions, whose symptoms may be foretold; particularly the healthy and morbid animal poisons. The contribution, however, which is often made by other causes as to the intensity and complications of exact diseases is well manifested in epidemic scarlatina, epidemic measles, and epidemic dysentery (§ 630 e, 663, 827 e, 961-970, 1002-1005).

652, c. The precise vital influences of any remote cause, their dependence upon the exact nature of that cause (all other things being equal), is critically displayed by the effects of slightly varied mechanical agents. Thus, "a mere prick or scratch is usually followed by cutaneous erysipelas; but not so with a deeper wound; and a punctured wound is less likely to induce it than a lacerated one" (§ 722, 725. Also, Med. and Phys. Comm., vol. i., p. 610; vol. ii., p. 474-480). And so in the same critical sense of the acclimated subject when a new epidemic influence may prevail, as set forth in section 551.

More striking distinctions, and according to the nature of the cause, are shown by such agents as opium, cantharides, mercury, the virus of snakes, of the mad dog, of small-pox, measles, scarlatina, &c.

The importance of enforcing this fact, in a practical sense at least, is shown by a common disregard of the subject, as occurs in the following example. Thus,—Pereira, in his erudite work on the Materia Medica, very justly says, that, "the precise pathological condition of the brain and spinal cord of an animal under the influence of hydrocyanic acid is matter of conjecture." But he adds,—"Whatever it may be, it is probably identical with that which occurs during an epileptic paroxysm, and with that induced by loss of blood." Now, loss of blood will often remove an epileptic paroxysm, at once; and is the best remedy for the cerebral congestion induced by hydrocyanic acid, after the depressing effect of the acid is over.

652, d. The physiological inquirer will not fail to apply the foregoing facts in opposition to the chemical and physical hypotheses of

life and disease.

653, a. Animal or vegetable poisons, if natural or healthy, are the product of natural organic actions; if morbid, they are generated by diseased actions; if altered from the foregoing conditions, they are

more or less the product of chemical decomposition.

653, b. Since, also, every specific disease requires its exact cause. and as every cause of disease which is elaborated by the living organism requires a certain precise state of the organic properties and functions for its production, (or if more or less of a chemical nature it has lost its original peculiarities,) it follows that the disease which is produced by a healthy animal or vegetable poison cannot be generated by a morbid one, and vice versa, nor can a chemical product become the cause of a disease which is induced by poisons that are exclusively the product of organic action, as in small-pox, measles, yellow and typhus fevers, &c. And since small-pox is produced by a morbid organic product, and can never, therefore, arise from another cause, and can be alone propagated by contagion, so, also, as the foregoing fevers depend, in certain known instances, upon the products of vegetable decay, they can never be of a communicable nature. Nevertheless, other causes may predispose the body to the operation of the more specific predisposing agents, so that small-pox, measles, &c., may be unusually epidemic and malignant (§ 630 e).

653, c. Healthy animal poisons, therefore, are never generated by the discased processes which they excite; but the morbid ones are reproduced by such processes, and by no other, and mostly by individuals of the same species, while the same law of individuality is

universal as to healthy animal poisons. .

653, d. For the foregoing reasons no contagious disease can ever be propagated by any other cause than such as is generated by that precise modification of the vital states which constitutes the essence of the disease. By the same inductive process all those affections which have for their causes the products of laws which govern inorganic matter can neither be regarded as contagious by the philosopher, nor shown to be so by the man who doubts every thing but his senses. The laws of life and the laws of chemistry are as wide as the poles from each other. No organic action can form the chemical combinations of dead matter, nor can the forces of chemistry imitate the mor-

bid any more than the healthy products of life (§ 43, 44, 52, 53, 150, 191 a, 409 c, d, 447 $\frac{1}{2}$ c, 630 e, 758, 773, 777–780, 1057 e–g).

Since, therefore, miasmata produce yellow fever, plague, typhus, &c., it clearly follows that the living system, when affected by those diseases, cannot generate a poison capable of producing the same affection in others, since the poison depended originally upon vegetable decomposition

(§ 657 b, 741 b). "Veritas latet in puteo."*

But, independently of this incontrovertible law which is predicated of numerous facts in physiology and pathology, and without one to invalidate its force, the whole of this question as to the contagiousness of fevers is settled negatively by a great variety of direct observations. (See Objections to the supposed Contagiousness of Yellow Fever, &c., in Med. and Phys. Comm., vol. i., p. 445-453, note, 532-534; vol. ii., p. 511.)—Also, § 1068 b, note. [Just now, 1860, suddenly abandoned.]

654, a. Specific predisposing causes, consisting of animal, and mineral, and most of the vegetable poisons, generally produce their sensible effects with great rapidity. Even vegetable miasmata, in a state of concentration, may determine an attack of idiopathic fever as soon as their operation begins (§ 648). It is upon this rapidity of effect that much of the utility of the materia medica depends (§ 554). I have accumulated examples of this nature in the Medical and Physiological Commentaries (vol. i., p. 471-474, &c.). But as no small number believe, with Louis, that "it is not true, as has been said too often, that facts do not become old, and the immense majority of them have become so; and, moreover, those which we collect in these times. will, in like manner, in their turn, become old" (the "numerical method" to the contrary notwithstanding, ibid., vol. ii., p. 810), I shall, I say, in view of this skepticism in respect to "facts" (§ 51, a, e), present an instance fresh from Bombay (1846) relative to the malignant cholera, and as yielding "food for the mind contemplative." Thus, the writer:

"Who shall depict the scene in the hospitals? I speak more of the Fusiliers, because of that I saw much; every cot was filled—delirium here, death there—the fearful shrieks of pain and anguish. Men whom you had seen a short time before hale and strong, were rolling in at every door, crowding every space—countenances so full of misery—eyes sunken and glaring, shriveled and blackened cheeks. This, too, the work of five short minutes or less! So sudden was death with some, that they were seized, cramped, collapsed, dead, almost as fast as I have written the words. Previous health and strength were no guaranties; men attending the burials of their comrades were attacked, borne to the hospital, and buried themselves the next morning. Pits were dug in the church-yard morning and evening; sewed up in their beddings, coffinless, they were laid side by side, one service read over all."

The foregoing paragraph, as well as the facts to which I have just referred, in another work, may remind the reader of what has been said of the action of hydrocyanic acid, nux vomica, &c., and lead him to appreciate the analogies in the modes in which morbific and remedial agents bring about their results, and strengthen his philosophy of the properties and laws of organic beings (§ 494 dd, 827 d).

654, b. The foregoing, however, is not equally true of morbid animal poisons, which are alike specific. I may also say, as farther il-

* A remarkable plagiarism of the foregoing argument (§ 633 a-d) was exposed by a correspondent in American Medical Gazette (N.Y.), December, 1859. "Veritas vincit."

lustrative of great vital laws, that morbid animal poisons have, commonly, the remarkable attribute of producing their sensible effects at more determinate periods than any other predisposing causes, with & few exceptions like the hydrophobic virus. It is also another striking fact, that natural small-pox occurs in about fourteen days after exposure, but that the intermediate period is only eight days where the same disease is communicated by inoculation. The disease, too, is violent in the former, and comparatively mild in the latter case; thus showing that slight variations in the condition of the predisposing causes will not only vary the duration of the predisposition, but modify all the phenomena of the ensuing disease (§ 650, 651). This is more particularly seen in the relative history of natural small-pox and the cow-pox, which are, essentially, one disease. It is an example, also, which illustrates the specific modifications of the properties of life in different animals; since we know of no other than the cow (certainly not the human species) that can so alter the variolous poison (§ 545. Also, Med. and Phys. Comm., vol. ii., p. 184, 195-200).

654, c. Again, there may be an interval of weeks, months, and years, after the application and the removal of the predisposing cause, before disease ensues. This is witnessed particularly in some remarkable exceptions which occur among the specific causes; as those which generate intermittent fever, while the same causes may also develop an attack with great rapidity (§ 654, a). "When a cause is applied which produces fever," says the philosophical Fordyce, "it produces it uno ictu, although the cause be no longer applied. Neither is it increased, diminished, or altered, by the farther application

of its cause."

654, d. Where the sensible effects follow rapidly the application of the causes, the predisposing is generally adequate to the full production of disease; and it may be equally so where the interval is longer, as in small-pox, hydrophobia, &c., though more commonly some exciting causes are necessary, as probably in a large proportion of idiopathic fevers. Hence, an attack of these diseases may be often prevented by a proper regimen, but not by medicine.—Note S p. 1124.

655. Specific causes commonly operate with greater certainty than the general (§ 646); and this is owing, in part, to the circumstance, that the former generally act both as predisposing and exciting causes. But, even the effects of these may be moderated by a proper regimen. Low diet, for instance, after exposure to small-pox, measles, scarlatina, &c., or after inoculation, or exposure to the causes of fever, will lessen the severity of the disease. The principle is the same as when a stimulant diet, &c., contribute to their production (§ 663).

656. The ordinary exciting causes, which, in their usual force, commonly fail of producing disease where a morbid tendency has not been induced by predisposing causes, may readily become predisposing, or

both together, by a greater intensity of action.

657, a. It commonly happens, especially in acute diseases, that, when predisposing causes are not followed immediately by a development of disease, the principal morbid states take place in organs distant from that on which the morbific causes exert their direct action. The main predisposition, therefore, is produced by reflected nervous action; and of course it is there that the principal explosion of disease takes place. It is subsequent to this, that the surfaces

on which the agents exert their direct action become sensibly involved in disease; and then it is probably quite as much a result of sympathetic reaction from the organs where the main explosion takes place (§ 148, 514 h, 524 c, 743). This is especially true of the alimentary and pulmonary mucous tissue, and of the skin, upon the former of which malaria appear to exert their direct action. The principle is seen distinctly in the pulmonic inflammation, rheumatism, &c., which follow the action of cold upon the skin, and in the application of mercurial ointment, and other unirritating remedial agents, to the undenuded surface (§ 649, c). And so of other remedies addressed to the stomach. They commonly exert their most sensible effects upon the remote parts now rendered particularly susceptible by the presence of disease (§ 137, d). But examples of remedial influences more in point occur in subsequent sections (§ 902 m, 905). In respect to morbific causes, however, there may not exist any preternatural susceptibility of the distant parts, but the agents establish their effects in conformity with laws already indicated (§ 150, &c.). The propagation of their influences in the foregoing manner is replete with problems of the deepest interest in medicine, and reason is often conducted to the truth by a firm hold upon a long chain of analogies. In this way, for example, we arrive at a knowledge that hydrophobia follows the law of propagation by nervous influence. The hydrophobic virus establishes certain imperceptible morbid influences upon the bitten part, which are by reflex action propagated over the system; and here, as in miasmatic fever, the predisposition is sufficiently formed in various other parts as not to require, for the general explosion, a full development of disease in the bitten part. There are commonly present, however, in hydrophobia, symptoms which denote either inflammation or morbid irritation of the injured part, just antecedently to the general explosion, which is precipitated by it. Hence, also, the reason why the removal of the bitten part, many days, or even weeks, after the infliction of the wound, may prevent hydrophobia; which it would be absurd to explain by the humoral philosophy of this disease (Medical and Physiological Commentaries, vol. i., p. 499-505).—Note D.

657, b. It will have been seen that a peculiarity attends idiopathic fever in its universal invasion of the body (§ 148, 757, &c.); and this leads me to indicate a certain difference in the sympathetic propagation of the predisposing influences from what may obtain in the more circumscribed forms of disease. In the operation of the predisposing causes of fever, the reflected nervous influence from the direct seat of morbific action gives rise to coincident pathological states throughout the system, where there is no interference from inflammation or venous congestion; while other morbific causes are apt to result in various modes of disease, as the effects of sympathetic influences radiated from their seat of action. In the former case, therefore, the general extension of reflex nervous actions is equivalent, in principle, to a specific universal action of the original predisposing

cause (§ 228, 653, 516 d, no. 6, 638½).

658. If disease be limited to the part on which the morbific cause makes its direct impression the changes may be then instituted by the direct action of the cause upon the organic properties, and without any necessary intervention of the nervous power. And so of remedial agents, as when caustic is applied to ulcers, unguents to the skin, &c. But,

It more commonly happens that the reflected nervous power is the immediate agent in the production or cure of disease, though seated in the part to which the morbific or remedial agent is applied. This reflection of the nervous power may come either directly through the nerves supplying the part, or from organs more remote (§ 184, 188, 205-216, 222-233\frac{4}{5}, 475-492, 493 cc, 500, 514 b, 647\frac{1}{2}, 893\frac{1}{2}, 902, 905 a).

659, a. Predisposing causes are often involved in much obscurity, especially when of a complex nature. Their operation may have begun at some remote period, and there may have been a long consecutive series without much relation to each other. Neither may be sufficient to lay the foundation of disease; but each renders the properties of life more and more susceptible to morbific influences from other causes, but which, otherwise, might have been innoxious. These new causes being applied, one after another, alter more and more the natural condition of the vital properties and functions, till, at last, some new, and perhaps as mild a cause, produces a sudden explosion of disease. This last cause is often mistaken, and often fatally for the patient, as the principal, or only source of a malady which has been the slow consequence of a long series of causes. And so of the last remedy, after a series of remedial influences.

Thus it frequently happens that the first in the chain of predisposing causes begins in childhood, and the last does not take place till adult age. The gastric and hepatic inflammations which supervene on the indigestion of adult life have often grown out of improper food in childhood, and a neglect of other natural habits, which are continued till habitual indigestion sets in. It then becomes difficult, from the influence of habit, to accomplish a cure; and these patients, too often indisposed to exercise self-denial, go on with persevering indulgence, and carry forward the morbid changes till obstinate and even disorganizing inflammations ensue (§ 548). Such, too, is the frequent history of intemperate drinkers, excessive tobacco chewers and smokers, opium eaters, &c.; the poison being slowly morbific in all the cases, but aided in its operation by many concurring causes (§ 524 c, 527 b, d, 548, 578, 630 e, 714, 902 c, m, 905 a, 970 c, 1066).

From this combined series of causes, and their gradual influences upon the vital conditions, there is every variety and gradation, as to number, time, activity, &c., down to those which, like a scald, or the bite of a venomous snake, develop inflammation at once, or, like prussic acid, extinguish on the instant, and without any other antece-

dent change, the entire powers of the organic being.

659, b. The foregoing gradual operation of morbific agents lays the foundation of the scrofulous diathesis (§ 836), and is analogous, in principle, to the philosophy of acclimation, and to the formation of artificial temperaments (§ 558, 560-563, 591). The causes, indeed, being perhaps not remarkably different, and only morbific under special circumstances, may transform the melancholic into the sanguineomelancholic, or into the nervous temperament, instead of producing chronic indigestion, or some habit of feeble health (§ 535-540, 602).

660. In the last section we have examples of what is in constant progress in disease, namely, the predisposing influence which a diseased organ exerts on others which were not diseased. These morbific reflex actions, leading to various sympathetic diseases, then fall within the category of predisposing causes; as may also the resulting

diseases; but, if they concur only in a secondary manner with other causes, then they may be only exciting, or both exciting and predis-

posing causes (§ 143 b, 222-232, 514 h, 647, 715).

661. Finally, all those hereditary peculiarities, in which there is a natural tendency in the vital states to take on diseased conditions. may be included under remote predisposing causes. But this is rather for the sake of convenience, since, in the hereditary constitutions, the tendency to disease is virtually no more than the common predisposition to disease, and is equally owing to remote causes which have exerted their predisposing effects upon our ancestors. It is convenient, therefore, to assume these transmitted peculiarities as equivalent to the remote causes themselves. And, although we cannot trace out the remote influences which lay the foundation of the scrofulous constitution, or of other hereditary predispositions, the known characteristic peculiarities of the accidental constitutions is equivalent to a knowledge of the nature of the remote predisposing causes; since in other affections we do but employ our knowledge of the predisposing causes in finding out the exact pathological character of disease. And so, also, of the several temperaments (§ 561, 585, &c.).

662, a. A knowledge of the remote causes of diease is often indispensable to the successful treatment of disease. Catarrh, for instance, arising from cold, in a sound constitution, although prolonged, may be suffered to pass without much remedial care; but, if it have for one of its remote causes a natural tendency to pulmonary phthisis, it should awaken all our vigilance for its removal. The reason is obvious. In the ordinary catarrh all the remote causes soon cease their operation, exert no profound nor specific changes, and the vital states soon obey their natural tendency to the standard of health. In the other case remote causes had been in prolonged operation, are more or less of a specific character, and the resulting predisposition has almost the fixedness of the temperaments (§ 543, 548, 561, 562, 585, &c.). In these cases, therefore, the tendency of nature is to go the wrong way; and in proportion to this she requires the intervention of art. We must then make repeated impressions upon the diseased conditions before we can establish the artifical changes, before we may counteract the naturally morbific tendency. This being accomplished, a favorable inclination is given to the balance of nature, and she comes in with languid efforts at restoration.—Note F.

662, b. Again, a fever, or inflammation, with partial remissions, presents itself. The fate of the patient may now depend upon our knowledge of whether the principal remote cause consisted of marsh miasmata, or of some other morbific agent, although it have long ceased to operate; since, in the former case, the Peruvian bark, arsenic, &c., may be indispensable, while in the latter they would be destructive (§ 870). It often happens, also, where the remote cause is still in operation, that its removal alone, especially those of a general nature, may be all that is necessary to a speedy cure (§ 648, 815).

Venous congestions, as will be seen hereafter, may be also attendant on intermittent fever, which shall ultimately require the Peruvian febrifuge, but which would be aggravated in most other cases. After bloodletting, it is the great remedy for the intermitting apoplexies of Italy, &c. In all these cases, the congestive affection is peculiarly modified by the nature of the predisposing cause (§ 816, 817).

• 662, c. Again, it has been always found, on dissection, that delirium a potu was attended with venous congestion of the brain; and such is the modifying influence of the remote cause that one of its frequent remedies is opium, and in quantities that would induce another modification of the same disease if administered in healthy states of the system, and for which bloodletting and coffee would be the remedies. This peculiar fact impresses us forcibly as to the wonderful modifications which different morbific agents establish in particular forms of disease, and enforces the importance of ascertaining the nature of the predisposing cause. Striking examples occur in the self-limited diseases (§ 858, 861). In delirium a potu antiphlogistics should prevail.*

663. The remote causes which readily produce disease in one man may not in another. Thus, during the prevalence of an epidemic fever, or the malignant cholera, or influenza, a greater portion of the inhabitants may escape the disease. There is, therefore, something appertaining to that part of the multitude which escapes that enables them to resist the morbific effects of the prevailing remote cause (\S 648, b). And here observation, as well as vital philosophy, enables us to understand the reasons, and how epidemics may be baffled.

We find, for instance, in respect to yellow fever, and all other congestive fevers, prevailing epidemically, that their subjects are apt to live on, after the appearance of the distemper, without much regard to their habits. They eat as freely as usual of animal food, drink their wine, and perhaps more ardent spirits. Others have become infirm from irregular habits, and such are, in consequence, rendered more susceptible of the epidemical influence (§ 827 c. e).

On the contrary, we observe that the class who escape are more generally abstemious, eat less stimulating food, or renounce it altogether, abandon all alcoholic liquors, avoid the night air, retire early

to rest, &c. (§ 615, &c., 623-625, 645 b, 630 e).

And so, where there exist constitutional or other tendencies to disease; its attack may be averted by habitually avoiding many agents which are inoffensive to others (§ 150). Peculiarities in respect to temperament are, also, often concerned in the degrees of susceptibility to the influence of morbific agents; just as they are in respect to remedial. The sanguine, for example, will be more the subjects than the melancholic or the phlegmatic; and the former require greater vigilance as to exciting causes (§ 551, 597, 598).—Note Oo p. 1141.

664. Certain predisposing causes sometimes extinguish the susceptibility to their morbific action even in concentrated degrees when they have been long in operation in degrees less intense; as in acclimation, the use of tobacco, &c. (§ 544, 545, 551). Some other causes always, or nearly so, destroy the susceptibility to their action through all future time after having once produced disease. These consist, mostly, of a few morbid animal poisons; namely, of small-pox, measles, scarlatina, hooping-cough, and mumps. It is remarkable, too, that all these diseases are contagious without contact, and are the only ones to which this combined law applies (§ 545, 654 b).

665. Predisposition often remains after disease shall have been apparently eradicated; as seen particularly in intermittent fever, and in chronic indigestion (§ 514 g, 560). This persistence of predisposition is most likely to occur where some organic derangement may have supervened, or where a low chronic state of disease may estab-

^{*} In the Med. and Phys. Comm. (vol. 2, p. 485-491), I have shown that tart. antimon., cathartics, and often bloodletting, are generally the best remedies for delirium a potu (§ $1058\,y$).

lish itself in some comparatively circumscribed part, and which not only contributes to maintain the general predisposition, but afterward increasing, becomes one of the exciting causes of another attack of fever (§ 806). These local conditions are generally owing to imperfect treatment; to the neglect, perhaps, in intermittent and remittent fevers, of proper depletion, or to the use of excessive doses of quinia, &c. Acquired predisposition to particular diseases, however, often appears to be almost as firmly ingrafted upon the constitution as those of an hereditary nature, with intervals of apparent absence of all disease § 535, &c.). Acclimation is also a study for the philosopher (§ 554).

666, a. Predisposition to disease consists in some indefinite change which has befallen the organic properties, and corresponds, in a general sense, with the peculiar virtues of the predisposing causes (§ 650, 652). Where the subsequent development of disease is severe, and especially if sudden, there has been, obviously, some profound antecedent impression upon the properties of life, instituted by the local operation of the remote causes, and propagated to other parts by alterative reflex actions of the nervous system. In fevers, especially, obscure symptoms may be seen some time before the sudden and full explosion of disease (§ 143, 227, 500 dd, 514 g, 685, 686, 764, 777, 785, 807, 811).

A morbific impression being once made on the changeable properties of life it may go on increasing in intensity, although the remote cause have been early withdrawn, till, having acquired a certain degree of force, disease may either explode spontaneously, or some mild exciting cause may institute a sudden and violent change in the now highly-susceptible properties of life (§ 506, 512–514, 516 d, no. 6, 518 b, 561, 618 a). At other times the predisposition appears to be stationary, perhaps for months, and even for years, as seen in fevers and hydrophobia; the former having been known to exist in a dormant state for a year or more, and the latter for seven years.* In these cases, it appears ultimately to assume, of itself, a tendency toward a full development (§ 148, 514 g, 559, 561, 715, 826, 657 a).

666, b. A distinct apprehension of the nature of acquired predisposition to disease may be had by referring to the philosophy of artificial temperaments (§ 591, 602, 603), and to those naturally modified states of the vital properties which so frequently result in hereditary diseases; as in scrofula, gout, bronchocele, &c. In some of those natural conditions which predispose us to specific modes of disease (§ 661) there is no apparent departure from a state of health, unless disease be developed by exciting causes (§ 645, c); and this will be true in proportion as the predisposition is limited to a few parts, and especially if those few be not important to organic life. Thus, the predisposition to gout is greatly limited to the small joints, though it may affect other parts, especially the intestinal mucous membrane. So, in bronchocele the predisposition resides in the thyroid gland. In such constitutions, therefore, there is not generally any thing present, under ordinary circumstances of health, to denote any modification of the properties of life which approximates a condition of obvious disease. These cases are so far closely allied to those conditions in which the predisposition to fever, or to hydrophobia, is in a state of incubation for many months, or for years (\$ 238).

But, in scrofulous subjects it is generally otherwise; since in those who are naturally predisposed to scrofula the tendency to the disease

^{*} An apparently clear case in London Lancet, February 3, 1838.

is more or less universal, and may affect almost every tissue and organ. There is, therefore, a natural radical fault in all the organic endowments of the system, and this fault or natural modification constitutes the predisposition (§ 661). Hence, in such subjects, the very elements of the body are diverted more or less from their perfect standard, and the union of their compounds into tissues and organs deviates, more or less, from that of natural subjects (§ 220). Irritability, especially, is not only permanently turned from its natural character, but is at all times preternaturally susceptible; and hence it happens that occasional causes, innocent in health, operate now with morbific effect (§ 143–150). These cases approximate those acquired predispositions where incubation is of short duration, and where there can be no doubt that the organic properties sustain a profound lesion during the early operation of the predisposing cause, or take on, at an early time, a progressive tendency toward an explosion of disease (§ 76, 181, 638½, 645 c).

II. PROXIMATE, OR PATHOLOGICAL CAUSE.

667. The *proximate* cause, as implied by the term, is that from which all the direct phenomena of disease arise. It must therefore constitute the essence of disease itself; and hence I substituted in the Medical and Physiological Commentaries the term *pathological* for proximate, and have since retained it as more expressive than the

original name when used in the sense here intended.

668. The remote causes, by their action upon the properties of life, lead to that change in their condition which forms the essential pathological cause, or the essence of disease (§ 644, 658, 666). As a necessary result, there also follows a corresponding change in the functions over which the properties preside, and therefore a more or less modified action of the vessels which are the instruments of disease (§ 247). All the symptoms, altered secretions, lesions of structure, &c., are only consequences, more or less remote, of those primary changes.

669. Since, also, it appears that all remote causes which differ in their virtues, or in their modes of influence, establish changes in the properties and functions of life corresponding, in a general sense, with the nature of the causes, and with the modes and intensity of their operation, it follows that the pathological causes, or results of the predisposing, must vary in a corresponding manner (§ 650, 651).

670. But there are many remote causes that are so nearly allied in their morbific virtues that they must produce pathological conditions of near resemblance. Such are the various remote causes of inflammation, and that other class which gives rise to idiopathic fevers. Since, however, many of the causes belonging to each class have certain very peculiar virtues of their own, there must necessarily arise corresponding peculiarities in the pathological conditions which they produce. Hence the very obvious differences which prevail among inflammations and fevers; though more or less is due to the nature of the affected parts, and often to many contingent influences. Inflammation of the venous tissue, for example, presents a combination of phenomena that distinguish it at once from inflammation of any other tissue, though the remote causes be the same. Much of the variety in congestive fevers is also owing to some inflammatory

state of one or more organs; while, also, venous inflammation is variously modified, as in all other tissues, according to the nature of the remote causes (§ 132-140, 149-152, 652, 722, 765, 766. Also, Med.

and Phys. Comm., vol. ii., p. 427-514).

671. Summarily, then, the precise nature of the pathological cause will depend upon the nature and action of the remote cause, or their combined nature when two or more operate efficiently, and upon the natural or other antecedent modifications of the vital properties of the affected parts, and the general nature and vital relations of any compound organ of which an affected tissue may form a component part; subject, however, to modifications from temperament, age, hab-

its, &c. (§ 150).

672. Every disease consists of a succession of pathological causes, till they end in health, or in death. These changes are the result of the natural mutability of the properties of life, especially when once diverted from their healthy standard. The morbid states are rarely stationary from one hour to another. They fluctuate, favorably, from the inherent tendency of the properties to return to their natural condition, or from artificial impressions from remedial agents; or, unfavorably, from the intensity of disease, the force of predisposition and of habit, or from the continued operation of predisposing or exciting causes, &c. (§ 177-184, 535, &c., 666, 733 e). The progressive changes may be gradual, and require but slight modifications of treatment, or great and abrupt; and either condition may follow the same morbific and remedial agents, according to the surrounding influences.

The absolute condition of disease, therefore, is changing not only spontaneously during its progress or decline, but is variously modified by remedial agents, and by other contingent causes (§ 733, d).

673. It is to the actual condition of disease, and the organs involved, that remedies should be directed. A knowledge, indeed, of the seat of disease, and of its exact pathology as far as may be attained, is often indispensable to a successful treatment; and here a knowledge of the remote causes may contribute the greatest light (§ 650).

So, also, at every successive application of remedial agents the new pathological conditions should form the ground of the new pre-

674, a. Upon the modified conditions of the properties of life, or their pathological states, therefore, all the modified actions of the vessels which are the instruments of disease, all the vital phenomena, and all the physical products depend; just as the healthy actions, phenomena, and products depend upon the same properties in their state of health (§ 177, 410). It is for this reason, the modification of the vital properties in disease, or the essence of disease itself, is called the proximate or pathological cause; all the rest being merely results or effects.

But, there are only certain facts that may be understood in relation to the changes which the organic conditions sustain from the operation of morbific causes. We can see distinctly that they are exalted in inflammation, and exalted or depressed in fevers. But these are comparatively unimportant elements of the changes. There is also the greater change which consists in some absolute modification of the nature of the properties, some positive change in kind (§ 177 666). What that change is it is impossible to comprehend, though it

be the essential part of the disease. We know nct, indeed, the absolute nature of the vital properties in their healthy state, and have, therefore, no standard of comparison in disease. We may, nevertheless, by the phenomena, as of all other forces of nature, learn all the laws of the vital properties, and the modifications to which they are liable (§ 234). The physiologist, I again say, concerns himself about the facts, the anatomical medium, the existence of the forces and the laws which they obey. He interrogates not the intrinsic nature of the powers, nor the proximate modes in which the results are produced.

674, b. For the purpose of having some visible or tangible condition before us in considering the pathology of disease, we often include some of the results as elements of the proximate cause, or even substitute some of the results for the cause itself. Thus, increased action of the capillary blood-vessels is often said to be the proximate or pathological cause of inflammation, though this is only a consequence, however a necessary one, of a certain morbid alteration of the vital properties of the vessels concerned in the morbid process. So, the pathological cause of venous congestion is said to consist in an accumulation of blood in the veins, though this is a very remote consequence. As a better designation, according to my exposition of the pathology, and since venous congestion is assumed as a particular disease, I would say, for the sake of brevity and convenience, that its pathological cause is sub-inflammation of the veins; the accumulation of blood being only a remote effect. And so of active phlebitis, or of any other inflammation which derives its name from the part affected. Such, indeed, has become the specification of common inflammation in almost every part of the body. But, in all these cases, inflammation is an aggregate term which stands for that change in the organic properties which is the true pathology.

674, c. But what is the pathological cause, in the foregoing comprehensive sense, of other diseases, as fever, &c.? Here we have less light as to the nature of the changes, even of function; and hence there is less guide from general principles, and more abstract dependence upon symptoms and experience. Still, as will be seen, the pathology and treatment of fever are not without their important general precepts. We reach a knowledge of the modifications which the physiological laws undergo, and this is the most that we require for

the institution of medical principles.

674, d. The vital states of a part or of the whole system may be variously modified in their condition so as to approach nearly to actual disease, and yet the modification fall short of the absolute change. This has been already seen in what I have said of predisposition to disease, whether accidental or hereditary. It is also constantly illustrated by the manner in which the heart sympathizes with every part which may be the seat of morbid action, and upon which the variable state of the pulse greatly depends. This prominent demonstration of reflex nervous action may be carried to all other organs, which, in like manner, are liable to sustain sympathetic disturbances short of disease, but according to their own natural modification of the properties of life, especially of irritability (§ 133–136, 188). And, although these conditions do not amount to absolute disease in its common acceptation, they may reverberate morbific influences upon parts sus-

taining a greater lesion, and often call for the intervention of art (§ 714, 848). Or, such influences may give rise to severe forms of disease in other parts. Thus, gastric derangements, not inflammatory. may induce severe inflammation of the mucous tissue of the throat, or hepatic or cerebral congestion, &c. (§ 500, 689 l). Again, certain morbific causes, acting upon the stomach, make their principal demonstrations in remote parts; as the narcotics, cantharides, &c. A simple element of this is constantly seen in the manner in which cold on striking the skin will develop catarrh, pneumonia, &c.; though, in the former cases, there may be specific relations of the morbific agents to particular parts, while in the latter, other predisposing causes may have operated (§ 147-151, 649 c, 657, 722 b). This principle lies at the foundation of all the consecutive developments which may spring up in different parts as the consequences of some primary derangement of a particular part, or of some local morbific impression which may come short of apparent disease in the organ impressed.

In sections 143, 666, 847, 848, I have endeavored to show how the whole system may be brought, by reflex nervous actions, into that condition, and how, in consequence, remedial agents will then exert a salutary effect upon all parts, when they might fail of any effect upon the same parts in their state of health; and how, also, in consequence of such remedial influences, the morbidly sympathizing parts may be made the sources of salutary reflex actions upon the primary disease; as may, also, such as have not sustained a morbific influence

(§ 514 h, 638½, 657 b).—Note D p. 1114.

675. As illustrative of some of the foregoing sections, particularly the last three, I shall now present an example of a therapeutical nature, but which takes, in its comprehensive range, the causation and philosophy of disease, the principle upon which morbific and remedial agents operate, whether directly upon the vital properties or through the medium of the nervous influence, the analogy between the operation of morbific agents and remedies, and how the last may prove, through a common principle, either remedial or morbific.

I shall assume, for the foregoing purpose, the intermittent fever, in which the whole system is engaged; and to simplify the treatment, bloodletting, nauseants, and quinine, may be the agents employed. Each of these agents, like all other therapeutical means, operate entirely upon vital principles, as set forth in the appropriate places in this work. Will the chemist and humoralist give their attention?

Now, without the aid of the philosophy which has been hitherto considered we could not comprehend, in the least, any of the phenomena of this disease, much less their consecutive relations, as they are regularly presented at the several stages of the complaint; nor could we any better understand the salutary or the conflicting results of our remedial agents. But, the true philosophy of life places the whole subject in a consistent, intelligible, and even sublime aspect. At each of the several stages of an intermittent, the properties of life are in different states of modification, and the remedies must be adapted to their particular modification at the different stages of the disease; or such as may be curative at one stage will either fail of their effect at all other stages, or exasperate the complaint. In the first, or cold stage, the properties of life are profoundly altered; and, as this is the beginning of the paroxysm, the alteration has not ac-

quired that fixedness, or that influence of habit, which results from its prolongation (§ 535, &c.). Powerful impressions may, therefore, be made upon the morbid properties, and, if rightly made, they may at once arrest the paroxysm. But no remedy can be applied with safety at the cold stage which would add to the excitement if applied at the hot stage. No stimulants, therefore, not even quinine, which is so eminently curative during the intermission, can be employed in the cold stage without proving morbific, and an aggravating cause to the hot stage. But, many remedies which are appropriate to the hot stage will tend, more or less, if applied during the cold stage, to produce a change that will mitigate the hot stage, or bring on at once the sweating stage. Of the three remedies proposed, there are two which will often accomplish this result, and cut short the disease at this stage of the paroxysm, or at least conduct nature to an immediate consummation of her cure in the sweating stage. But, the nearer the beginning of the cold stage either of the two remedies are applied, whether loss of blood or an emetic, the more salutary, for the reason already stated, will be their effect. Numerous and striking examples of this important principle might be stated; as, for instance, an emetic will often subdue, at once, pneumonia or croup, if exhibited at their very invasion, when it may be perfectly powerless in a few hours afterward. And so, in a more limited sense, of the abstraction of blood, which reaches more profoundly and more universally all the organic properties, and determines upon them, when syncope approaches, a greater and more universal impression of the nervous power (§ 947, 948). This remedy, therefore, may often answer well at any period of the cold stage, should we determine upon its use.

But, suppose that the hot stage supervene. A new condition of the vital states has now sprung up, and it must be treated accordingly. Whatever will lessen and otherwise favorably modify irritability (§ 188, &c.), and contribute to the production of the sweating process, will be salutary at all periods of the hot stage, and whatever increases irritability and mobility will, as at the cold stage, exasperate the hot stage and embarrass the sweating stage. It is evident, therefore, that quinine will still prove morbific. But we have in certain nauseating remedies, as tartarized antimony, and in bloodletting, appropriate means for reducing and otherwise modifying the morbid state of irritability, in the hot stage. Alterative doses of antimony, even short of nauseating, may now exert a powerful tendency to bring about that favorable change which ensues naturally; while in its full emetic dose, so often favorable near the invasion, or at the onset, of the cold stage, this agent is rarely useful and frequently injurious. Abstraction of blood has the same useful tendency. But, this remedy, unlike its effect, and that of emetics, in the cold stage, will not operate with the greatest force at the beginning of the hot stage, but near the termination of this stage in the sweating process. The properties of life have now assumed a radically different condition. They are rapidly throwing off the influence of predisposition and of morbid habit, and their tendency is toward a restoration of their natural state. Nature is therefore more successfully aided in this new condition as she approaches the sweating or more curative process, which is the final cause of the hot stage. Hence it follows, where the advantage of one impression only can be had from a remedial agent, although it be useful, like bloodletting, at other periods of this stage, it should generally be delayed, at least, till the stage of excitement has reached its acme. If cathartics be employed at this stage, they should be delayed, at least, till the sweating process has begun; and now an emetic may be sometimes salutary. But, the former, partly on account of their irritation, should rather be deferred till the sweating stage is over, while emetics are most salutary just before the invasion of a paroxysm, which, as in the hot stage, is always an inauspicious time for cathartics.

In proportion as nature is going on with a progressive march toward a comparatively healthy result, as in the sweating process, there should be no great interference from art. No help is wanted, for the restorative process will be soon spontaneously completed, and, at an advanced stage of this process, and before it is finished, there will be always danger of making some unfavorable impression, unless it be from remedies of a mild character, whose uniform result is that of acting as sudorifics, and coinciding in other respects with the changes which are in progress during the sweating stage. Such a remedy, for

instance, is tartarized antimony, in doses short of nausea.

Finally comes the interval of repose, which is remarkable for its specific, but various, duration; giving to intermittent fever its quotidian, tertian, or quartern type. There is, however, notwithstanding the apparent state of tranquillity, very often some morbid condition remaining; as sufficiently denoted by any subsequent return of the paroxysm. In all such cases, there is a progressive change going on in the vital properties from the time of their comparatively natural state at the close of the sweating process toward that profoundly morbid alteration which constitutes the cold stage. The disease is again in a state of incubation, and therefore the tendency to change in the organic properties is exactly the reverse of what had just antecedently existed during the hot stage and its termination in the sweating process (§ 666). It is now the object of art to prevent a repetition of the paroxysm. This may be often accomplished by mere rest in a horizontal posture, and abstinence from all solid food; for the tendency of nature may be the right way, if she be not embarrassed by exciting causes; the slightest of which, as a shock of the mind, may throw her into a state of incubation. This shows not only the great susceptibility of the vital properties, during the intermission, to morbid changes, but, also, their frequent disposition to return, unaided, to their natural state. Should they require any other intervention from art than the mere act of withholding exciting causes, it is manifest, from what I have now said, that slight influences from remedial agents will be amply sufficient; so only we discard pernicious causes, and there be no severe local disease. The remedies for this purpose consist of a group that are called specifics, and have been suggested by experience independently of any general principles; so very peculiar is the state of the vital properties during the period of intermission. Of these specific agents the Peruvian bark and its alkaloids is one, arsenic another, and cobweb another; coming severally from each of the three great kingdoms, and each exerting nearly an equal control over the progress of incubation, but without any other known analogies to each other; certainly none of a chemical nature. The quinine, or arsenic, which would have been surely morbific at any other stage of the paroxysm, may

now be employed with a remarkably curative effect. But, a great error is often committed in exhibiting quinine, in this very tangible state of the organic properties, in excessive quantities; by which the disease is either prolonged, or the predisposition only temporarily subdued, or local affections induced or aggravated. As an invariable and important rule, also, just in proportion as the organic properties are approaching a state of health, so should our treatment be cautiously mild, or it will light up disease (§ 764. Also, Med. and Phys. Comm.,

vol. i., p. 443, &c.).—Note K p. 1119.

676, a. In the foregoing section I have stated a problem for the specific object of showing the variety of changes which diseases are liable to sustain in their pathological character during a short period of their progress, and the importance of adapting the treatment to the changes which may ensue, with no other reference to symptoms than as they are indicative of the seat of disease and its true pathology (§ 762). But I have also, incidentally, at the same time, demonstrated the absurdity of attempting any part of the problems of disease, or the modus operandi of remedial agents, by any philosophy borrowed from the inorganic world, or by any hypothesis in the humoral pathology. The vital solidists, however, being numerically small, claim to be little ceremonious with error; and once more, therefore, I shall bring into contrast the adverse doctrines ($\S 350\frac{1}{4}-376\frac{1}{2}$, 433-450). With this intention I shall submit the philosophy as now taught in Great Britain and France, and leave it to the reader to interpret by that philosophy, if he can, the problems contained in the last preceding section.

676, b. It is scarcely necessary to remind the reader that Liebig's speculations in medicine are in general vogue in Great Britain (§ 349, d), and have become incorporated in medical works of every description (§ 433). Take the following example, relative to my present topic, from the long-celebrated and able, but now completely met-

amorphosed, Pharmacologia of Dr. Paris (§ 339, b).

"In a recent work by Professor Liebig, to which I have frequently referred," says Dr. Paris, "we are presented with views not only applicable to the question under discussion, but well calculated to extend our knowledge with regard to the modus operandi of contagious matter, and its reproduction in the living body. I have already explained his important application of the dynamic law of La Place to chemical action; viz., that a body, the atoms of which are in a state of transformation, may impart its peculiar condition to compounds with

which it may happen to communicate."

Dr. Paris then proceeds to say, that it "was reserved for the genius of Liebig" to apply this doctrine of "fermentation," "putrefaction," &c., to the living body, in explanation of "the modus operandi of contagious matter," &c. I had occasion to set forth this philosophy of the Continental Chemist in my Examination of Reviews, together with the principal examples by which it was sustained (p. 55). Some of them occur, also, in the present work (§ 350, nos. 29 to 46, and 78 to 97). Of the "sausages," by-the-way (to illustrate the extent of acquiescence), it is said by Dr. Paris that, "by entering the blood, they impart their peculiar action to the constituents of that fluid, and all the substances in the body are induced to undergo a modified putrefaction" (§ 339 b, 349 d, 350, no. 44).

EЕ

I shall not pursue this subject farther, having, in the Medical and Physiological Communication (vol. i., p. 385-716), devoted an Essay to the merits of the Humoral Pathology, where all the foregoing points,

the "sausages," &c., are duly investigated (§ 282).

And now to complete this example of sudden and general illumination, and to exemplify, again and again, "the recent progress of medical science" under the auspices of "experimental philosophy," let unhear Dr. Paris as he was at a former edition of his Pharmacologia, and when he and others were just as much enlightened as to the connection of chemistry with the healthy and morbid processes of man as when he put forth the ninth and last edition of that distinguished work. Thus:

"Every rational physician must feel, in its full force, the absurdity of expecting to account for the phenomena of life upon principles deduced from the analogies of inert matter; and we therefore find that the most intelligent physiologists of modern times have been anxious to

discourage the attempt, and to deprecate its folly."

In descanting upon the interference of the celebrated chemist, Mr.

Brande, with medical topics, Dr. Paris remarked, that

"Whenever the chemist forsakes his laboratory for the bed-side, HE FORFEITS ALL HIS CLAIMS TO OUR RESPECT AND HIS TITLE TO OUR CONFIDENCE" (§ 709, 1006 a, 1034).

III. SYMPTOMS.

677. Symptomatology is the third and last division of pathology; being the doctrine of symptoms. It embraces all the phenomena which result either directly or indirectly from morbid states, and includes,

therefore, the physical as well as vital signs (§ 883).

678. During the healthy state of the vital properties all the results of life progress in one uniform way, according to the nature of the several parts of the organic being (§ 249). But, as soon as the properties of any part undergo changes there arise corresponding changes in the motions of the vessels, and in all the phenomena and products

(§ 177).

679. Now it is owing to the insensible, recondite nature of the efficient causes of all phenomena that we are compelled to apply ourselves to the study of the phenomena to obtain a knowledge of the powers or properties upon which they depend, the modifications which the powers or properties may undergo, and the laws which they obey. It is obvious, therefore, that the nearer the phenomena are to the direct operation of the causes the more significant will they be of their nature and existing condition. This undeniable fact shows us the superiority of the primary effects of disease, as a guide to pathological conditions, over those ultimate results which are disclosed by morbid anatomy.

680. In entering upon this inductive branch of pathology it is important to bear in mind, that, however complex the nature and variety of symptoms they have always as much an absolute cause as any effect in the inorganic world; and I am led to this remark for the purpose of adding another,—that it is of incomparably greater importance to ascertain the former than the latter. When motions are disturbed in the subordinate kingdom it is the first impulse of reason to trace out the cause; but that is the measure of its compass. The Power

that gave to matter its being, or natural influences, can alone rectify the cause. But, how different with organic nature! How expressive of the radical distinction between the causes of motion in the dead and the living world! In the latter all is fluctuating in its nature, yet all controllable in that very nature by the hand of man. We see in the principle of life the cause of organic results. We see those results vacillating in every possible aspect; and, as with the chemist, or the astronomer, in the former case, we interrogate the cause. But we do so with a far higher aim; for we know that the cause is amenable to rectifying influences. In the world of matter and in the world of life the causes of erratic phenomena may be on a par in principle. The disturbing influences may be alike due to a common cause in each department, respectively. But, in the mineral kingdom there are numerous fundamental causes in operation, and the phenomena, therefore, may depend upon opposing influences. In the organic, from the mushroom to man, there is but one cause; and hence the obvious induction that certain changes in the natural condition of that one give rise to all those diversified effects which form the transient phenomena of disease, or those more stable changes which are seen in the progress of the being from its embryo to its adult state, or in the vicissitudes of temperament, &c.

We therefore apply ourselves, I say, to the cause itself; and here all analogy disappears with any known cause in the inorganic kingdom. The former is changeable in its nature, and as the changes go on, its existence comes to an end. But the same First Cause Who imparted that instability for great and wise purposes ordained, also, that when the principle of life should be diverted from its natural condition by untoward agents, it should still possess, through the same law of mutability, a capacity of receiving impressions from other agents that shall awaken its inherent tendency to a state of integrity.

In tracing out the nature and the seat of disease through the attendant phenomena, we are also animated with the conviction that organic beings are subject to laws as precise as those which rule in the inorganic world, under all their fluctuations; and the greater complexity in the elements of their laws than such as relate to physics and chemistry should stimulate the most exact investigation of symptoms wherever nature may demand the active interference of art, so

that the latter may make the best use of her laws (§ 237, 447 b).

681, a. The symptoms, or effects to be employed as guides to the nature and seats of disease, are, 1st. Those which are denominated vital signs, and which are independent of physical products. 2d. The changes of motion and other conditions relating to the vessels which are the instruments of disease, but which are independent of structural changes. 3d. The physical products which are comprehended under the denominations of secretions and excretions. 4th. Symptoms of the foregoing nature which are determined or modified by changes of organization, and about which morbid anatomy is interested. 5th. Signs of a physical nature which depend upon either some change of structure, or on the accumulation of fluids, or the presence of some unusual fluid, or other substance, within the body. These last signs come to us principally through the medium of sound and touch. The first three of the foregoing classes of symptoms may be denominated primary, the last two secondary.

681, b. The five divisions into which I have distributed the symptoms of disease, and the remaining facts which we derive from morbid anatomy, and what we learn from remote causes, and the effects of remedial agents, supply all the knowledge we can obtain of the pathology of disease.

681, c. We must, therefore, constantly concern ourselves about effects, whether investigating the natural world, the powers by which

it is governed, or spiritual existences.

Symptoms, then, are the language of disease, as effects are of all

other real existences.

682, a. Certain symptoms are called diagnostic. By these, in part, we distinguish diseases from each other. A symptom, therefore, to be diagnostic, must be peculiar to one affection. Thus, hydrophobia is the diagnostic symptom of the disease which is called, like some other affections, after the name of its diagnostic. But it is only peculiar to the disease as it affects the human species. The diagnostic of intermittent fever is the intermission between the paroxysms; and so of their attendant intermittent apoplexies; and paroxysmal increase of those inflammations that are relieved by bark, and the intermission of periodical headaches, and of tic douloureux, are their diagnostics.

682, b. Some diseases may have several diagnostic symptoms. Thus, in pneumonia, a good diagnostic is found in the tenacity of the mucus. Another diagnostic is the crepitating noise which is heard on applying the ear to the chest. The first symptom, however, is often absent, and the other is not always present, especially in infants. The crepitus, also, disappears when condensation of the air-cells takes place, and this disappearance is diagnostic of condensation. But if the patient recover, the condensation generally disappears, and while the process of absorption is going on the crepitus returns, and this is diagnostic of the absorption. Many diagnostics are supplied by auscultation as to the particular parts which are affected in diseases of the heart, and which are significant of the precise nature of the affection. And so of the lungs. Percussion has also its peculiar diagnostic signs. We are doubtful, for instance, whether a tumid state of the abdomen be owing to flatulency or to something else. A hollow sound, on percussion, assures us that it depends, in part, at least, upon the presence of some gaseous substance.

682, c. Many diseases have certain symptoms which are nearly always present at certain stages of their progress, but are more or less attendant on some other affections. This is the case with the hectic fever of consumption. In such instances the other attending symptoms will determine whether the prevailing one in any particular affection is significant of that disease in the case before us. Incompressibility of the pulse is perhaps always significant of inflammation; but it often requires much skill to detect it. The attendant hardness of the pulse may be then taken as a good diagnostic; but this also is often ascertained only by a delicacy of touch, and may not be always distinguished from the pulse of pregnancy. An auxiliary diagnostic will then be found in a buffiness of the blood; but here, too, that appearance is often presented by the blood of pregnant females. There then remains an unequivocal diagnostic of inflammation in the associated cupping and fimbriated edges of the blood (§ 688, d, e)

On the other hand, there are many affections which have no diag-

nostic symptom; and we must then rely upon the combined symptoms, the remote causes, &c.

682, d. Such, then, are symptoms which impart a general apprehension of the nature of disease, or of its variations, &c. They serve as an aggregate of the other attending phenomena, and, in a general sense, should be employed only as starting points to a critical investigation of those numerous details which may alone conduct us to a knowledge of the extent and force of disease, its complications, &c.

683. There are other symptoms which are called *prognostic*. It is by these, in part, that we judge of the degree of danger, and of the probable issue of disease. Hence arise the terms favorable and fatal,

and various other expressions of an intermediate import.

684. We acquire our knowledge of symptoms, or deviations from the natural states of the body, by comparing the former with the phenomena of the latter; and we distinguish diseases from each other, and learn the changes which are in progress, by comparing symptoms with each other. By the same system of comparison we judge, also, of the effects of remedies, form our prognosis, &c.

685. It is evident, therefore, that the young practitioner, at least, should acquire a habit of methodical analysis of disease, with a steady view to its pathological cause, and the successive changes which may

arise in respect to this cause (§ 673, 675). He should begin,

1st. With an inquiry into the natural temperament of the subject, his age, habits, &c.

2d. Make a general survey of the symptoms, the organs from which they spring, their general aspect, number, variety, &c.

3d. In all cases of severity, the remote causes should be ascertain-

ed as far as possible.

4th. All the great organs should be next critically interrogated, that the primary seat of disease may be ascertained and understood, and how far it may have involved, by reflex nervous actions, other organs, both in their compound nature and in their individual tissues (§ 133, &c.), and how far, also, the sympathetic results may react upon the primary disease, or institute morbific reflex influences among themselves.

This inquiry embraces all the vital signs, the state of the secretions and excretions, and the physical signs afforded by auscultation and percussion. The countenance, the organs of sense, and all that relates to the external body, the state of the tongue, pulse, &c., should

come under review.

5th. A careful comparison of all the symptoms should be instituted with the analogous phenomena in health; with the symptoms of the same disease as it may affect other parts; with the symptoms as they may have been observed in various degrees and at different stages of the same malady; with the symptoms of convalescence; and with such as follow the action of medicines; and with the symptoms of other diseases.

6th. Inquire into the mode in which the symptoms occur, whether

suddenly or gradually, distinctly or confusedly, &c.

7th. Consider their progress, their changes, the mode of their prog-

ress, &c.

8th. Examine the relation of different symptoms to each other; as, their relative duration, order of occurrence, &c.

9th. Calculate the degree or force of the symptoms; a point of difficult attainment, requiring a correct appreciation of the properties of life, a profound knowledge of physiology, an extensive acquaintance with its modifications in disease, habits of a close analysis of symptoms, much thought, and a well-disciplined mind. To one thus qualified the eye of the patient alone may be a luminous index to the degree or force of the general symptoms (§ 163, 714).

686, a. And now, as a consummation, next to the direct application of remedies, of all that has been hitherto submitted to my reader, as immediately indispensable to the ultimate aim of all that has been said, and without which the Institutes of Medicine would only serve as an

intellectual exercise, I shall introduce a practical example, as a general standard for investigating any given form of disease with a view to its treatment (§ 714).

686, b. Let us, then, suppose ourselves called to a case of idiopathic fever of some three or four days' duration, in which, from the length of its continuance, there have probably arisen some local inflamma-

tions, and, perhaps, venous congestions.

We proceed, according to the foregoing method (§ 685), to inquire, 1st. Into some general facts, and take a general survey of the case. We inquire how long the patient has been sick, with what symptoms he was attacked, what new ones have subsequently sprung up. whether they have undergone an increase in the afternoon, and a decline toward morning, whether the attack was preceded by unusual sensations, or by any signs of beginning disease, what is his age, constitution, habits, &c. The knowledge thus acquired gives us a general apprehension of the nature of the case, and we come, at once, to the conclusion, that it is a case of idiopathic fever, affecting an individual of a certain age, temperament, habits, &c. This leads us to inquire,

2d. Into the nature of the predisposing causes (§ 662), and as they are atmospheric (§ 648, b), we ascertain his place of residence for a few preceding months. We find, perhaps, that he has lately come from a city where yellow fever prevailed, or had resided from one to six months ago where typhus was rife, or where it is known to occur, or from one to twelve months since he had been in some marshy district, or upon some new rich soil, where the remittent fever delights; or, there may be reason to suppose that the causes originated in the place where he is attacked. A knowledge of any of these facts, whichever may be true, goes far in ascertaining the particular modification of fever he may suffer (§ 650-653). Let us suppose him an Irish emigrant, just landed in New York. We suspect at once typhus fever, though we have no such fever originating with us.* It is a very common form of fever, however, in Ireland; and we learn farther from our patient that it prevailed in his neighborhood when he left that country. This knowledge influences our subsequent inquiries, when we proceed,

3d. To inquire specifically into the symptoms attendant on all the organs, and to compare them with the natural phenomena of each. We begin where they are most strongly pronounced, and pass from one organ to another as may be suggested by the most obvious symptoms, or as they may seem to be related by sympathetic influences (§ 660). The disease being typhus, the brain, or its membranes, are probably the seat of inflammation or venous congestion. We inquire

* See Note S p. 1124.

as to headache, whether obtuse or acute, in what part of the head. &c.; whether there be drowsiness or wakefulness; whether there be an unusual pulsation of the carotids, or of the temporal arteries, or an exalted temperature of the head; whether the face be suffused with blood, and if so, whether the plethora be in the arteries or veins,—being florid in one case and purplish in the other. We look critically at the eyes, observe how their lustre or other expression is affected; whether the pupil be dilated or contracted, and, if the sight be dim, we inquire whether it be owing to an affection of the retina, or how far to actual cerebral disease or to sympathy of the eyes with any gastro-intestinal derangement; whether the conjunctiva or the eyelids be red or purplish, whether moist or dry, &c. We attend to the hearing, whether dull or acute; observe how far speech may be affected, and how much any impediment may be due to cerebral disease, or to dryness of the mouth, or to inattention, &c. These inquiries relative to the senses should be accompanied by others respecting the mind, whether memory be much affected, perception and reflection impaired, whether there be hallucinations when awake, or talking in sleep, and whether sleep be comatose, or how long continued, &c. These inquiries may leave little doubt that there is both inflammation and venous congestion within the head, which will be cleared up by an investigation of symptoms relative to other organs (§ 803, &c.). Our attention may be next attracted to the chest by cough, or some embarrassment of respiration. We inquire when the cough began, what its frequency and severity, how far it may be independent, in its origin, of other local burdens of disease, or how far consequent on abdominal affections, and whether attended by expectoration, and what the nature of the matter expectorated. We count the respirations, and observe their equality or inequality. We see, perhaps, that the brain influences the respiration unfavorably, especially if slow, and this adds to our conviction that mischief exists in the head; or, if the breathing be hurried, it may be due to febrile excitement, or to abdominal derangement. The cough and expectoration show us that some inflammatory action is going on in the lungs; but we are doubtful, perhaps, on account of some thoracic pain, and as the sputa is rather adhesive, whether inflammation be confined to the mucous membrane of the bronchi, or have reached the air-cells and cellular tissue, and thus constituting pneumonia. We therefore resort to auscultation and percussion to resolve the doubt. From the former we learn that there is no crepitus, that the murmur is clear and free, and there is only a mucous râle; by percussion, we find that the resonance is good, and we therefore dismiss our fears as to the possible existence of pneumonia, or of tubercle. But the patient complains of pain in his chest. We ask him to breathe deeply, and the pain is much increased, as it is also on coughing. From this symptom, and the absence of pneumonia, we are sure of the existence of inflammation in the pleura, while the cough and expectoration tell us of catarrhal inflammation in the pulmonary mucous tissue.

It is now time to feel of the pulse, to learn how far reflex nervous actions may affect the heart and arteries, since the extent of the influences on the circulatory organs may show us considerably the severity of the local inflammations. But this system is also under the influence of the general idiopathic disease, and it is often one of the nicest

points to determine how much of its character is due to the febrile affection and how much to reflex nervous actions. And the difficulty is enhanced if influences are directly propagated abroad by cerebral disease. We find the pulse, perhaps, not so hard or full as we had expected, and this leads us to infer more of venous congestion than of ordinary inflammation of the brain; or, that there may be venous congestion in some other organ not yet examined, since these congestions are very apt to spring up in typhus, and to moderate a hardness of the pulse which the coexisting inflammations of the membranes of the brain and lungs would otherwise produce (§ 815, &c.). Perhaps we discover, also, in the pulse, some intermission or other irregularity in its stroke. This may be owing to some organic affection of the heart, and to resolve this doubt, we again resort to auscultation. We find, however, all the sounds good, and we are now led by the foregoing symptom, along with the subdued hardness of the pulse, and its want of any great incompressibility, to suspect venous congestion of the liver, since intermission and other irregularities of the pulse, without organic disease of the heart, commonly depend upon that state of hepatic disease, though, also, on cerebral inflammation; but in the latter the pulse is more frequent than in the former case, when, also, in the absence of fever, it is often preternaturally slow; or, if slowness of pulse depend on venous congestion of the brain, as it sometimes does, the respiration is also apt to be slow, while it is unaffected in simple hepatic congestion (§ 390, b). We then take the liver next in our range of inquiry. We find, perhaps, some obscure tenderness on pressing its region, and the patient may have had some pain in this quarter. We then look at the skin, to see whether there be any shade of yellow, and when our cathartics operate, we examine the discharges with various references, but particularly as to the state of the visceral secretions. If they are blackish, or green, this strengthens our conclusion as to congestion of the liver, though the congestion may be so profound that little or no bile is secreted. This condition of the liver, however, is more apt to attend remittent, intermittent, and yellow fevers. We observe whether there be a redundancy of intestinal mucus, as this would denote some inflammation of the mucous tissue, and has often an important bearing upon the treatment of the case, as does also that irritable state of the intestine which is denoted by the diarrhœa that often supervenes in the progress of typhus fever. We look at the urine, and find it perhaps scanty, scalding, very high-colored, and depositing a sediment. This, however, would imply nothing distinctly, but that the kidneys suffer in their powers and functions, though great scantiness of urine and a high color would denote a considerable burden of disease upon one or more important remote organs, and those particularly the digestive organs. We now turn our attention more particularly to the alimentary canal, partly with a reference to its morbid state, and in part to aid our judgment in the right administration of medicines. Here, too, we may find a great focus of disturbing reflex nervous influences radiating from the gastro-intestinal mucous membrane, lighting up inflammations or congestions of other parts, or maintaining and aggravating such as may have sprung from other causes, and sustaining itself reverberated nervous influences (§ 514 h, 647, 889 g). We press, for example, the region of the stomach, to learn whether it be

tender, and in like manner examine the whole, or special regions, of the abdomen, if there be pain or uneasiness in the intestines, &c., and we make percussion to see if there be flatulency. We inquire what food the patient has recently taken, and whether the bowels have been constipated or loose. In all this part of the inquiry we are often greatly aided by the appearances of the intestinal evacuations, which should be carefully observed throughout the continuance of disease (§ 694½). We also examine the tongue with a reference to several objects, but especially with a view to the condition of the stomach and intestines. We notice its color at its edges and in the centre; whether coated, and how extensively, and what the color of the coating in its different parts; whether light and loose, smooth or rough; whether dry or moist, and the extent of each; whether the tongue be enlarged or contracted, pointed or obtuse, smooth or indented at its edges, what its color, &c. We look at the fauces, to learn if they be red or purplish, as indicative of inflammation or venous congestion, or other derangement in the important organs below; observe whether there be glutinous matter on the teeth, and what its color, and the rapidity with which it may collect.

We now turn our attention more distinctly than before to the functions of the skin; whether it be dry or moist, or each alternately, and the duration of each, whether hot, warm, or cold, and at what times, and how long, whether the heat be distributed equally, whether the feet be cold when the rest of the surface is hot, whether the skin be rough or smooth, what its color, whether there be "sudamina," "rose-colored spots," &c.

The patient may require the loss of blood, and we observe its color, whether dark or florid, the manner in which it flows from the arm, whether in a full stream or whether it trickle, whether it throw up a buffy coat, be indented or cupped in its centre, or fimbriated at its edges; and, that these observations may be perfect, we take an ounce in a funnel-shaped vessel for examination (\S 682 c, 688 ee).

If, in the case of fever now under examination, there be a predommating influence of the venous congestions over the membranous inflammations, the blood will be dark, will trickle from the arm, or flow in a languid stream, at first, and will throw up a buffy coat, without as much indentation as when membranous inflammation exists without venous congestion.

686, c. The foregoing analysis of symptoms is, to the young practitioner, necessary to a clear apprehension of many severe diseases, but must be more or less varied according to the nature of the disease. It may be apparently tedious, but is accomplished with rapidity by a little practice. Nor have I stated all the inquiries which should have been instituted, and which may be of essential moment. Thus, it may be necessary to call in the aid of smell to ascertain whether any feetor we may observe come from the mouth, or stomach, or lungs, or from the surface of the body. The patient may also supply a variety of facts as to his sensations,—whether restless, weary, prostrated in his voluntary muscles, what as to pain, or sensations of heat, chilliness, &c. We vary his posture, to learn how it may affect respiration, or the state of his pulse. I have also left out of my examination of the

See Essay on the Writings of Louis, in Mcdical and Physiological Commentaries, vol. ii. p. 724, &c.

foregoing case an inquiry as to the mode in which the symptoms took place, -whether suddenly or gradually, distinctly or confusedly, whether they began with a chill, or with a paroxysm of heat, &c., about which the patient should be specifically interrogated. Nor did I examine sufficiently the relation of the different symptoms to each other, as their relative duration, their order of occurrence, &c., by which we ascertain which organ was first inflamed or congested, and what others are more or less affected by reflex nervous action. And there yet remains to be considered the progress of the symptoms, their mode of progress, their spontaneous changes, or such as may arise from incidental exciting causes, or from the action of remedies, &c., and, also, their comparison with those of other modifications of fever, or other forms of disease. I said nothing, specifically, as to an inquiry into the degree or force of the symptoms, which is always a subject for accurate consideration, as it goes far in denoting the severity of disease in different parts, and is one important guide to the nature and extent of the remedies. But this is an attainment, as already implied, which cannot be imparted by a description of symptoms, since their force cannot be expressed in language. Their estimate must come, as it were, by intuition. CHEMISTRY contributes nothing.

686, d. In proportion as our knowledge of physiology enlarges, and we apply it to the investigation of disease, the practice of a minute analysis of symptoms becomes less and less necessary. But, to acquire this professional tact or skill, we must first go through the school of elementary instruction and practice. But industry will at last triumph, and what seemed at first obscure in diseases may become luminous at a comparatively superficial view. We then begin to neglect, more or less, many of the minutiæ. We confine ourselves more to the most prominent or characteristic symptoms. The countenance alone may tell us of a labyrinth of disease. But, it will still often happen that no prominent symptoms are present, and it may then be necessary to go into the details; or they may be so confused and indistinct as to render us undecided as to the seat or the nature of the disease till other symptoms are developed. This may be illustrated by the growth of a plant. When it first emerges from the ground it may have no specific characters by which we can determine whether it be destined for a tree or a weed. We must therefore await the development of its characters, which, if it continue to grow, it will certainly put forth. There is often an obscurity of a like nature in diseases, at their early invasion, and even when profound. The soundest judgment may be baffled in the adaptation of certain remedies; and if these are to be administered internally, especially if active, no risk should be taken, but farther developments awaited.

OF CERTAIN SPECIAL SYMPTOMS.

687. It had been my purpose to have limited my remarks to the general principles which respect the present branch of my inquiries. But, in consideration of what I shall say of the pathology and treatment of inflammation, venous congestion, and fever, as also on the subject of bloodletting, I have determined to express my own views as to some of the symptoms which take a prominent rank in diseases. It is also my desire to associate the results of disease with the philosophy which concerns them, that these important sources of pathological

knowledge may be studied in connection with those inquiries which distinguish the philosophical physician from the mere empyric $(\mathfrak{5}^1_2, a)$.

The Pulse.

6871. There is one system of organs, particularly, whose motions are so constantly affected by reflex nervous actions, and whose phenomena are universally employed in estimating the nature, force, &c., of all diseases, and at all stages of their progress, and which are also elementary in denoting the effects of remedies, especially of loss of blood, that I shall make a general analysis of the prominent charac-We generally learn the influences exerted upon this system of organs by the varying states of the pulse, and the radial artery affords the best opportunity for this purpose, though the pulse may be often advantageously examined in other places. Thus, in inflammations and congestions of the brain it is useful to learn how far the pulsation of the carotids may be specifically affected. So, in similar affections of the liver we attend to any unusual pulsation of the aorta in the region of the stomach. In all such cases irritations are apt to be propagated by continuous sympathy along the principal communicating arteries, by which their action is more or less increased (§ 498). It may be also important, sometimes, to examine the heart itself, especially when it may be suspected of being the seat of absolute disease; and, although the pulse be generally regulated by the action of the heart, the arteries, as we have now and before seen, are liable to independent influences, arising from reflex nervous action, and from continuous sympathy. As to the latter, if there be inflammation of the hand or arm, we shall be very likely to find the pulse on that side with greater characteristics of disease than on the other; and differences will arise from mere differences in the size of the arteries. In inflammations and congestions of the brain, the nervous influence will often exert an effect, less marked in similar affections of other organs, upon the capillary vessels, and this effect is sometimes strongly pronounced by an inequality in the radial arteries (§ 929-936, 973, 974). In various forms of disease the heart sometimes beats with greater force than is denoted by the pulse at the wrist, and sometimes the pulse is very voluminous without a corresponding action of the heart, according to the nature of reflected nervous actions.—Note LL.

688, a. When the radial pulse is examined, the four fingers should be applied along the course of the artery, and various degrees of pressure should be made. The blood taken for examination should be into a conical wine-glass, and, if possible, in a full stream.

688, b. Certain general conditions of the pulse worth noticing are the following:—its quickness, slowness, frequency, hardness, softness, incompressibility, compressibility, fullness, smallness, strength, weakness, obstruction, freedom, intermission, redoubling, trembling, and other inequalities (See an extensive application of all this in $500 \, m$, $694\frac{3}{4}$, $826 \, cc$).

688, c. Quickness.—This term does not stand in opposition to slowness, although it is generally so considered. Frequency is the opposite of slowness. Quickness arises from the systole of the heart occupying less time than its diastole; so that a quick may be a slow pulse. The stroke is then sudden, the dilatation more prolonged, with an interval somewhat distinct. A frequent pulse, on the contrary, is always what the term denotes. The systole and diastole of the heart succeed each other rapidly, and in about equal times.

A slow pulse is, also, like a frequent one, uniform as it respects the systole and diastole, both of which are prolonged. It is most apt to be attendant on chronic venous congestions, though, as the affection advances, or undergoes any sudden increase, it may become frequent. When slow in such conditions, the pulse is also often intermittent or otherwise irregular, and if it subsequently become frequent, the irregularities are apt to disappear. Venous congestion is always to be suspected, and especially in the liver, when the pulse is preternaturally slow, without other manifest signs of disease (§ 390, b).

Quickness of pulse is not an important symptom, in a general sense. 688, d. Hardness and Softness.—These terms stand in opposition to each other. Softness is a natural state, and hardness a morbid one; though a pulse may be preternaturally soft. Hardness of pulse is one of its most important modifications. In nearly all cases it is indicative of inflammation, and no considerable inflammation can exist long without producing it. It appears to depend upon some direct modification of the action of the vessels, and not connected with that of the heart; the nervous influence being determined in a peculiar manner, by inflammatory affections, upon the whole arterial system (§ 226, 233, 973, &c.). The term hardness may be well understood by comparing the sensation to that which is produced by a solid rod rising simulta-

neously, and not successively, against the four fingers.

688, dd. Hardness is often confounded with strength and fullness; but the three symptoms are very different from each other. A hard pulse is perfectly compatible with smallness and weakness; the former of which is seen especially in peritoneal inflammation of the intestine, and in pulmonary consumption; the latter in unsubdued inflammations after repeated abstractions of blood, and often in congestive fevers, and in phlebitis. To distinguish the hardness fully, in these latter cases, requires a careful regulation of the pressure; scarcely more than a gentle touch with the four fingers. Greater pressure may extinguish the symptom, and the pulse may even appear to be soft. The distinction is often of great importance, especially in congestive diseases, as upon it may depend the decision of those who are apt to be governed by the state of the pulse in the important matter of blood-

letting (§ 961-965, 971).—Note Ll p. 1140.

688, e. Compressibility and Incompressibility.—Incompressibility of pulse is probably peculiar to inflammatory conditions, and one of the most uniform characteristics of the pulse when such conditions disturb the general circulatory system by reflex nervous actions. But when inflammation is fully overcome, especially if general bloodletting have been freely practiced, the pulse is often more easily compressed than in health. So long, however, as the disease continues to affect the general circulatory system, that peculiar characteristic remains, in various degrees, unless the remedies be very depressing, or the powers of life verging toward a state of extinction. But, as might be expected from what I have said of hardness of pulse in venous congestions, incompressibility is less marked in all forms of venous inflammation than in equal conditions of inflammation of other tissues. Here, too, as with hardness of pulse, the observer is very liable to be deceived; since the general volume of the pulse may give way under a slight pressure, and yet the pulse be incompressible (§ 688, d).

The proper method of ascertaining this symptom, in doubtful cases,

is to make a hard pressure with one finger, and a moderate pressure with another on the distant side, when a thread-like stream will be felt by that finger. It depends upon reflected nervous influence.

Hardness and incompressibility generally demand the loss of blood; though whether local or general, and the necessary extent, must be determined by other symptoms; the extent, especially, by the effects produced during the operation of general bloodletting (§ 826 cc).

688, ee. Coincident with hardness and incompressibility of pulse, and almost peculiar to inflammation, is the buffy coat, with its depressed centre, and often fimbriated edges. The buff which forms on the blood in pregnancy is due to the increased vascular action of the uterus, and a modification of its vital properties not very dissimilar to what obtains in some varieties of inflammation, and which predisposes to those active forms of the disease which so often beset the uterus and other parts in the early stages of childbed; and should the indented centre and fimbriated edge make their appearance, we shall scarcely fail of deriving farther confirmation of the actual presence of inflammation in an attendant hardness and incompressibility of the pulse, and probably, also, in some local symptoms. And so of the buff which is sometimes apparently consequent on violent exercise; but more probably dependent upon some obscure inflammation. We may not trust, in these rare instances, to the carelessness of many observers, and the incapacity of others, while the fact should not be neglected that this exception to a significant indication for loss of blood has been raised by such as are adverse to the use of the lancet in the treatment of inflammation (§ 826 cc, 952, 1020–1024).

The indentation, or cupping, is generally less strongly pronounced after each abstraction of blood, and may disappear altogether, under

the lancet, before the inflammation is subdued (§ 952 b).

The fimbriated edge is most common where inflammation is severe, and has established a strong reflex nervous action upon the general circulatory system. In such cases, also, it will often continue to occur after the cupping ceases to be formed.

Like hardness and incompressibility of the pulse, the buffing and cupping of blood, for reasons already stated, are less strongly marked

in venous congestions than in membranous inflammations.

The formation of the buff, and the central depression, and the fimbriated edge, are remarkably affected by the shape of the vessel, and by the manner in which the blood flows from the veins. A shallow vessel is the worst, the form of a funnel is the best.

688, f. Fullness and Smallness of pulse.—These terms are also in opposition, and both may imply a preternatural state of the pulse, being now employed in their morbid acceptations. Fullness is also

synonymous with largeness.

These morbid states of the pulse are owing to reflex nervous actions determined both upon the heart and arteries. The extent of these influences, in that respect, is very variable, and must be judged of by direct examination of the pulse at the heart and extremities.

It does not necessarily follow that an unusual quantity of blood is sent out by the heart, since the volume of the arteries may depend greatly upon a direct expansion of the vessels. So in a small pulse, the direct morbid influences may be more upon the arteries than upon the heart, by which the vessels are held in a contracted state.

This is especially seen in the cold stage of fever, and in peritoneal enteritis. It is also seen in the depressing states of venous congestion. In all such cases an influence is propagated from the arteries to the heart, by which, as well as by other influences, its action is accelerated; or, if not accelerated, then the blood accumulates in the venous system, especially about the right cavities of the heart. In all these cases there are profound reflex nervous actions well worthy an inquiring mind (§ 222, &c., 514 d, k, l, 914-919, 929-936, 973, 974).

Smallness of pulse is generally a much more important symptom than fullness; commonly implying the presence of greater evil. Connected with hardness, it is always bad, when it is also frequent.

688, g. Strength and Weakness.—I have already remarked that these symptoms are often mistaken for hardness and softness. They depend, principally, upon reflex nervous actions that are exerted upon the heart by remote organs, though certainly not altogether. It is doubtful, indeed, whether morbid reflex nervous actions are ever exerted upon the heart without being simultaneously extended, more or less, to the arteries; especially to the capillary series (§ 481-485, 973, 974). But, all parts of any one division of the arterial system may not be equally affected, or one part may be sensibly affected and not the rest, as in blushing, when the nervous influence is direct. 688, h. Obstruction and Freedom.—Obstruction is an obscure con-

688, h. Obstruction and Freedom.—Obstruction is an obscure condition of the pulse which it is difficult to describe, but is recognized in practice. It is not easy to know its cause, as it probably does not actually arise from any obstacle to the passage of the blood, though it may be owing to a want of harmony between the action of the

heart and the capillary blood-vessels (§ 386).

688, i. Frequency and Slowness.—These are two very important symptoms in some of their morbid aspects, and are often replete with information, especially as to the force of disease and the degree of danger.

To ascertain these characters, the patient, for obvious reasons,

should be at rest; and if a child, should be asleep.

No writer has so well described the conclusions to be derived from a *frequent* and *slow* pulse as Dr. Heberden, in his "Commentaries." From their importance, and as I cannot improve Heberden's descrip-

tion, I shall quote it.

"The pulse of a healthy infant asleep," he says, "on the day of its birth, is between 130 and 140 in a minute; and the mean rate of the first month is 120. I have never found it beat slower than 108. During the first year, the limits may be fixed at 108 and 120. For the second year at 90 and 108. For the third year at 80 and 100. The same will very nearly serve for the fourth, fifth, and sixth years. In the seventh year the pulsations will be sometimes so few as 72, though generally more; and in the twelfth year they will often be not more than 70; and, therefore (except only that they are much more easily quickened by illness, or any other cause), they will differ but little from the healthy pulse of an adult, the range of which is from a little below 60 to a little above 80. It must be remembered that the pulse becomes more frequent, by 10 or 12 in a minute, after a full meal. [Müller, remarkably, states the same rates].

"If the pulse either of a child, or an adult, be quickened so as to

exceed the utmost healthy limit by 10 in a minute, it is an indication of some little disorder. But a child is so irritable, that, during the first year, a very slight fever will make the artery beat 140 times, and it may beat even 160 times without danger [Heberden meaning either idiopathic fever, or the constitutional effects of inflammation]; and, as there begins to be some difficulty in counting the pulse when the motion is so rapid, the thirst, quickness of breathing, aversion to food, and, above all, the want of sleep, enable us, better than the pulse, to judge of the degree of disease in infants.

"If the pulse of a child be 15 or 20 below the lowest limit of the natural standard, and there be, at the same time, signs of a consideraole illness, it is a certain indication that the brain is affected, and consequently such a quiet pulse, instead of giving us hope, should alarm

us with the probability of imminent danger.

[An important exception to the foregoing remark is frequently presented by venous congestions of the liver, when the pulse may be equally diminished in frequency, but not indicative of present danger.]

"In adults ill of an inflammatory fever, the danger is generally not very great where the beats are fewer than 100;—120 shows the beginning of danger; and they seldom exceed this number unattended with some deliriousness. There are two exceptions to this observation. The first is, that before some critical swelling or deposit of matter begins to show itself in fevers, the pulse may be so rapid and indistinct, as hardly to admit of being counted; and I have known it certainly not less than 130, and yet the patient has recovered. And rheumatism affords a second exception; in which the artery will often beat above 120 times without any sort of danger.

[Those exceptions are relative to inflammation as limited to parts unimportant to organic life. They are presented, also, in other in-

stances of this nature, and in intermittent fever.]

"In an illness where the pulse all at once becomes quiet, from being much accelerated, while all the other bad signs are aggravated, it is a proof, not of a decrease of the disorder, but of the lessened irritability of the patient, and that the brain has become involved in the disease.

"In low fevers, and in exhausted old men, the pulse will often continue below 100, or even 90, and yet the disease be attended with want of sleep, deliriousness, restlessness, and a parched tongue, and end in death, without any comatose or lethargic appearances.

"A pulse increased in frequency more certainly denotes danger than a natural one does security, where disorders of the viscera are

suspected."

Finally, in countries where local congestions of the liver occur, as in the regions of intermittent and remittent fever, the pulse often falls, in hepatic congestions, far below its natural frequency. Considered abstractedly in these cases, and often in the preceding, it affords but little information as to the force of disease. There may be great danger, or but very little, when the pulse is slow in hepatic congestions, and all other symptoms obscurely marked; but if the slowness be supported by restlessness, sighing, thirst, wakefulness, &c., the danger is great.

A good pulse, excepting a moderate hardness, and incompressibility, as sometimes happens in pneumonia, may be attended with great

danger, which can only be inferred from other symptoms. Indeed, I may say in a universal sense, that the state of the pulse alone should rarely guide our conclusions, either as to the force of disease, or its treatment. The circulatory organs are so readily and variously disturbed by the nervous influence, and that influence so constantly generated by physical and mental causes, that disease offers but few opportunities when the pulse may be safely trusted for the just application of remedies without the support of other symptoms (§ 826 cc, 829).*

688, k. Intermission.—An intermitting pulse arises from an abrupt suspension of a pulsation of the heart. It is not an alarming symptom, unless it depend upon some organic affection of the heart, or some disease of the brain. It is a frequent attendant upon venous congestions of the liver, and often presents itself for the first time after the patient becomes convalescent, and may continue till the flesh and strength are restored. It is most apt to appear when the pulse is also preternaturally slow, and frequently vanishes temporarily if the circulation happen to be accelerated by transient causes, or a great irregularity of the pulse may be the temporary consequence. Its philosophy is explained in a foregoing section (§ 390, b).

688, l. Irregularities of pulse.—These consist of irregularities in its successive beats, redoublings, trembling, hobbling, &c., and are rarely of much importance unless proceeding, as in cases of intermission,

from organic affections of the heart, or disease of the brain.

The Tongue.

689, a. We will now turn a brief attention to the morbid appearances of the tongue. It is by these, and the secreted products, that we obtain our most direct intelligence from the internal viscera, though other less sensible results may be more significant of the nature and force of disease.

689, b. The tongue is covered by a secreting membrane, whose action is liable to great and various changes, and which are attended by visible results. In its healthy state this membrane is covered by a thin fluid, which is partly composed of its own mucous product, and, in part, of saliva. The natural color of the tongue is a light florid hue, and it is studded with short minute papillæ, particularly at its edges. In disease these appearances are apt to undergo various changes; the tongue being often covered more or less extensively with a coat of variable hues, white, yellow, brown, or black, barely attached, or closely adherent, rough or smooth, &c. At other times the organ is preternaturally red or livid, dry or moist, enlarged or contracted, pointed or obtuse, its natural coat thickened or apparently scraped off, or covered with patches, vermiform marks, &c., its edges jagged, the papillæ enlarged and elevated, &c. These conditions depend upon various modifications of the organic functions of the tongue; and as the organ is not much liable to independent disease, it is obvious that its morbid aspects are mostly sympathetic results; and from its being continuous with the alimentary canal and the lungs, morbific influences are readily propagated upon it from either of its remote connections (i). But, the vital relations of the tongue to the alimentary canal are far greater than to the lungs, though not strongly pronounced in health; and as intestinal derangements are more common than pulmonary, a far greater proportion of

^{*} NOTE LL p. 1140.

the morbid and intense influences from these two sources are exerted by abdominal disease (§ 129 i, 135, 142).—See INDEX II, Art. Tongue.

689, c. The coating which forms upon the tongue may consist mostly of mucus, or of a substance resembling coagulable lymph, or intermixtures of both, in various proportions, and of a morbid character.

689, d. All the phases which the tongue is liable to undergo may be influenced by the peculiar constitution of the patient, though in a general sense, where the constitution is sound, these appearances are less subject to the contingencies of temperament than many other symptoms.

689, e. We often observe, under various circumstances of disease, that the coating has suddenly disappeared, and we may be led into error in consequence, since, in many of these cases, the coating has

been removed by the mechanical friction of food.

689, f. It would be in vain to attempt a definition of the various changes in the aspect of the tongue which are produced by disease, according to its nature and seat, accidental causes, &c. The appearances may vary much under apparently the same conditions; and it is not one symptom alone which may attend the tongue, but the whole in combination, that must guide our judgment. It is important, also, to observe that the tongue may be very natural in profound diseases, even of the alimentary canal and liver; but as observation enlarges, and the depths of physiology are explored, we shall find the morbid signs of the tongue a luminous index of disease.

689, g. But, there is one remark more important than the rest; namely, that there are no other symptoms which borrow so much light from others as those which relate to the tongue; while, in their turn, they reflect back a light upon the other symptoms. Inflammations of various parts, and idiopathic fevers, at their onset may present nearly the same appearance of that organ, especially as it regards the coating. The general symptoms now contribute largely in determining the import of the tongue; though we shall generally find, on close suspection, that not only each class of diseases will offer certain peculiarities in the morbid aspects of the tongue, but as inflammation may affect one important organ or another; and the appearances will vary in the early stages of idiopathic fever as the burden of disease may happen to be distributed. In the progress of the same affections, the tongue is continually fluctuating in the indications it may supply.

689, h. The disappearance of the coating in fevers and inflammations generally begins at the edges of the tongue, and is commonly indicative of an improvement of health, though not always. When these exceptions occur some other morbid appearance is apt to follow immediately; as preternatural redness, or nakedness, or dryness, &c. If indicative of improvement the tongue commonly clears up fast, along with other auspicious changes; though it will be frequently kept up, more or less, by remaining though slight visceral derange-

ments in the abdomen.

689, i. Absolute diseases of the digestive organs affect the tongue more variously and distinctly than other parts; according to their nature, seat, intensity, duration, peculiarities of constitution, habits, &c. (§ 129 i, 142). In indolent affections of the stomach, a thick, dirty, yellow coat, easily scraped off in part, appears particularly

FF

toward the root of the tongue; when, also, the tongue often becomes furrowed, or covered with patches of various forms, indented at its edges, or apthæ arise; the coat, too, varying according to the varying states of the intestinal canal, or of the liver, &c.

689, k. If the tongue be very red, it denotes more or less active inflammation of some part of the intestinal mucous tissue; and if also dry, and especially if at the same time denuded, it shows inflammation of greater intensity in that membrane. A tongue preternaturally naked, even if moist, and of no great redness, shows moderate or sub-inflammation of the mucous tract; probably of the small intestine. A livid tongue shows venous congestion of the alimentary mucous membrane, and probably also of the liver. It is always indicative of formidable disease.—See Index II, Art. Tongue, Heart, Kidney, Pulse.

689, l. In connection with the foregoing subject I may advert to an inflammatory state of the mucous tissue of the fauces which ensues upon congestive affections of the chylopoietic viscera, and which is too often regarded as an independent disease, and treated accordingly. But, the condition of which I speak is so comparatively unimportant with the primary affection upon which it depends, and is so often sig nificant of the force of obscure, but dangerous forms of abdominal con gestion, especially of the liver and intestinal mucous tissue, that I would rather place it among the symptoms than designate it, in its true character, as a sympathetic form of disease. This inflammatory affection is commonly of an erysipelatous nature, attended by more or less tumefaction of the tissue, and often of the tonsils. It varies greatly in intensity, and presents different hues from bright scarlet to livid; the latter being the worst, and denoting a profound and dangerous modification of venous congestion (§ 813-816). In its worst forms, the throat is quite liable to ulceration, and often to sloughing. In the latter case it is commonly denominated the "putrid sore throat," and, most unhappily, this symptom, as it were, has been extensively regarded as the main disease. These appearances of the throat are also a common attendant on bad forms of scarlatina, and are due to profound congestion of the liver and intestinal mucous tissue, associated, more or less, with a peculiarly modified form of inflammation of the same tissue (\S 803, 816 b). The whole of this secondary evil is, abstractedly, of little comparative moment, and is analogous in its import to those forms of erysipelas which affect the surface when this symptom is epidemic (§ 463 a, 523, no. 7, 630 e, 713, 961 a, 970 c)*

Secretions and Excretions.

690. The secreted and excreted products, which fall under the cognizance of the practitioner, are messengers of intelligence either directly from the citadel of disease, or from organs which participate sympathetically with affections of other parts, or which may scarcely do more than minister to the general wants of the body. They are, therefore, to be received according to their several degrees of importance. They consist of urine, sweat, mucus, and the alvine discharges.

691. The Urine.—No product is so variable as the urine, both in health and disease. The kidneys, being designed for great and immediate common purposes in the animal economy, in depurating the blood, or in transiently fulfilling the office of the skin, &c., are rendered highly sensitive to the presence of redundances in the blood, and

* Such, also, is equally true of the various phases of Bretonneau's DIРИТИЕКА, and which is generally considered a local or a humoral affection.—Note Kk p. 1140.

to the variable states of other parts, especially of the skin, whose analogous office is so liable to interruption. The same Great Intelligence, which ordained these final causes, also endowed the kidneys with a stability of function unknown to other parts (excepting the heart, for a like principle), where irritability is easily impressed. Being, therefore, but little subject to actual disease, the variable product of the kidneys commonly supplies only a report of the nature of the ingesta, or of the influences which the skin or other parts, and even the mind, may exert upon these organs in a healthy state, or of the mutable states of the body in regard to nutrition, or of any disturbing reflex influences, short of disease, which may be extended to the kidneys by diseases of other parts (§ 426). It is thence obvious, that but little dependence, in a general sense, can be placed upon the sensible changes of the urine as indicative of the nature or force of disease; and I have endeavored to show, here and elsewhere, that we may rarely trust to chemical analyses of this product (§ 417, 427). Beyond a transient inspection, occasional evaporation is about all that we require, unless, also, some practicable test in calculous affections. The aspects of the urine become more important in renal diseases, and in those of the bladder. Albuminous urine appears in organic affections of the kidneys, in dropsy, and after pastry and other indigestible food, and is produced by mercury and cantharides. It is evident, therefore, that the presence of albumen, about which so much has been written, indicates nothing specifically, unless supported by other symptoms (§ 421-427. Also, Medical and Physiological Commentaries, vol. i., p. 674-682).—Vide LEHMANN, p. 780.

A sensation like that of *strangury* is often felt when the urine is high-colored and scanty. This is commonly owing to abdominal dis-

ease; particularly hepatic congestion.

692, a. Sweat.—The perspirable matter is the least important of any of the tangible products of disease, unless as it respects the amount of sweat in its connection with the other attending symptoms, or as significant of the effects of certain remedial agents. Not much can be inferred from its quality, and this little is gathered from its taste and odor. Dryness of the skin is oftener an important character; and it is usually one of the best signs supplied by the skin when its dryness yields spontaneously. Perspiration induced by medicine is of little moment, unless the remedy simultaneously impresses, directly or indirectly, the parts diseased; and then the salutary results, so far as the surface is concerned, depend upon special vital influences exerted by the remedy upon the skin, and reacting sympathies. This is exemplified by the profound effects of tartarized antimony and ipecacuanha, the uselessness of hot water, and the frequent pernicious results of the compound powder of ipecacuanha, when free perspiration may follow the administration of either (§ 514, h). The effect, therefore, upon disease depends but very little upon the evacuation from the skin, as produced by what are called sudorifics; but upon the peculiar action which may determine the evacuation, and its consequent alterative reflex nervous influences. And this, by-theway (for these opportunities may not be neglected), shows us the futility of the chemical hypothesis of the formation of the secretions.*

692, b. Though sweating be generally a symptom of good omen, it may be one of the worst. Thus, a person suddenly falls down, in-

^{*} See Note D p. 1114.

sensible, and copious perspiration ensues. It may be death from hemorrhage, or from a sudden cessation of the action of the heart, or it may be temporary syncope. Again, profuse perspiration often appears suddenly in protracted stages of disease. If the other symptoms are bad, the sweating is still more so. In these cases the pulse is generally small and rapid. But it sometimes denotes the near extinction of life when the pulse gives no sign of danger, and the sweating may be even considered favorable if the whole circumstances of the case be not carefully weighed.—A viscid state of the perspiration is commonly significant of great force of disease. In some fatal cases of the cholera asphyxia there was only an insensible perspiration, throughout (In my "Cholera Asphyxia of New York," 1832).

693. Mucus.—The mucous tissue being every where more or less exposed to irritating agents is naturally protected by mucus, as the skin is by the cuticle; but only in quantity sufficient to cover the surface of the membrane. When, therefore, it is continuously discharged from the nose, expectorated from the lungs, or voided by the intestine, bladder, or uterus, it denotes a morbid state of the tissue; and that state is of an inflammatory nature. This is plain enough in respect to the nose, throat, lungs, and bladder; but the analogy is neglected in relation to the intestine, where it often supplies an important indication in the absence of other prominent signs of inflamma-tion. This morbid organic product is liable to great varieties in its appearance and properties, each one of which depends upon a special modification of inflammatory action (§ 409 h, 410, 415, 682 b). Its exact condition will also conform to the natural modifications of the vital properties of that portion of the tissue which may be the seat of disease. Hence, in part, the varieties attending the morbid conditions of mucus, as it may proceed from the eye, nose, throat, lungs, and intestine (§ 133-135, 682 b).

Unlike the excrementitious products urine and sweat, the product of the mucous tissue, like all other organic compounds, is uniformly the same in health in the same parts of the tissue, nor is it liable, like the former, to undergo chemical changes as soon as secreted (§ 417). Its morbid changes are determined by the same precise laws as is its natural condition, and therefore each change depends upon some precise accidental modification of the vital properties and actions, and according to their natural modification in the part from which the discharge may proceed. Could we, therefore, always ascertain the precise character of its morbid changes we should arrive as nearly as possible at the particular condition of the existing disease (§ 237, 682 b. Also, Med. and Physiolog. Comm., vol. ii., p. 197, note).

694, a. Alvine Discharges.—The fæces consist of the superfluities of food, and the remains of various secreted products which are poured into the intestine from the liver, salivary and pancreatic glands and mucous tissue. But, neither the bile, nor saliva, nor intestinal mucus, nor the gastric juice, appear in the fæces in their natural state. Combined, however, with the fæces, they offer a general natural standard for comparison with the morbid conditions.

694, b. In disease, the foregoing natural conditions as to quantity and quality of the secretions, and the state of the residual food, are more or less affected, according to the nature of the morbid states which may attend the various parts concerned in digestion. From the

number of organs, therefore, that are liable to be simultaneously involved in morbid processes, and which contribute their fluids to the alvine dejections, as well as the imperfect changes which the food undergoes in the stomach, it would seem more difficult than it is, in reality, to derive any just conclusions as to the nature of disease from the condition of the fæces.

The following are the most important signs to be noticed in the al-

vine discharges:

1st. The Residual Food.—This gives us intelligence as to the state of the stomach. It is mainly important in chronic affections of that organ, or during convalescence from acute disease; since, till the subsidence of acute diseases, the food should consist mostly of fluids, whether the stomach be the direct seat of the affection, or disturbed by reflex nervous actions, or liable to irritation from solid food in the absence of those conditions (§ 512, 514 h, &c.). We may be thus guided, also,

as to the food which should be avoided.

2d. The nature and quantity of the matter discharged.—This, in acute diseases, will consist, principally, of the secreted fluids, which, so far as produced, may cease to be in any way appropriated, and accumulate in the intestine, though much, in respect to the apparent accumulation, may be due to the absence of residual food with which the secreted products are habitually intermixed. Their deficiency, during the operation of a cathartic, denotes severe disease in the organs of digestion, especially the glandular, or that an unsuitable cathartic has been applied. If the evacuation be large, watery, and colorless, the cathartic was bad. It has irritated, morbidly, the intestinal mucous tissue, has not reached the glandular function of the liver, or may have propagated injurious influences upon that organ. If a judicious cathartic have been employed, and not in excess, and mucus alone follow, it shows inflammation of the intestinal mucous tissue, and disordered action, probably congestion, of the liver (§ 693), which will be aggravated by a repetition of cathartics till the disease be lessened by other remedies; of which general bloodletting, leeching, and blistering, are the principal. Or delay of all remedies may be sufficient (§ 856, a). Again, a redundancy of bile may be either unfavorable or favorable, and its proper interpretation may depend upon a variety of considerations; such as color, the period and past history of the disease, the general and local vital signs, the nature of the remedies, especially of the cathartic, employed, &c.

When the bile is redundant, the mucus is apt to be at least natural in quantity, and when the latter is in excess the bile is commonly deficient, since, in the latter case, the formation of bile is diminished by morbific reflex nervous actions propagated upon the liver by the mucous tissue. It is the same as when morbidly-irritating cathartics diminish or stop the secretion of bile. And here I will say, that I am far from meaning alone what are denominated the drastic cathartics; since calomel, blue pill, and even the neutral salts, may be more morbific in a given state of disease than scammony, colocynth, aloes, and

especially jalap, in doses of corresponding energy (§ 889 g).

When the secreted products increase after having sustained a diminution, the sign is, perhaps, always favorable; but how far so will depend upon other symptoms, and upon the amount which is due to nature. In some hepatic congestions cathartics procure but small

evacuations till the disease is considerably overcome. The secretions then start, become abundant, long continued, and a salutary bilious diarrhœa sometimes sets in. The same is also true of jaundice, whether arising from disease of the liver, or from obstruction by gall-stones.

3d. The appearance of the fecal matter as to color.—This is a very important index in many respects. We should distinguish carefully, however, what may be owing to color of food, or what may be im-

parted by medicine, from that which is morbid.

If the discharges be light it shows a suspended secretion of bile, which may be owing to the irritation of an improper cathartic, or to inflammation of the intestinal mucous tissue, or to inflammation or congestion of the liver, or to jaundice, &c., and the other symptoms will clear up our knowledge upon the subject. In all these cases, as disease gives way the bile is secreted in redundance, is apt, at first, to be blackish, or of a deep green, then changing to brown, or to a

dark yellow, till it finally becomes of a lightish yellow.

Calomel and acids are very generally supposed to render the bile green. This they will do when mixed with the bile out of the body; but this chemical effect is counteracted by vital resistances afforded in the intestinal canal, just as putrefaction is arrested in food by the same agencies (§ 339, b). No quantity of calomel will impart a green color to the discharges of a healthy subject, nor will any acids; being an inquiry which I have sufficiently submitted to experiment. When, also, the bile becomes redundant and yellow during the decline of abdominal disease neither calomel nor acids will affect its hue, unless a morbid irritation be produced. At the onset of disease there may be no green appearance of the dejections till calomel or blue pill be given; but the reason is, that, till then, the secretion of bile was suspended, and what was accumulated in the gall-bladder is now dislodged. The mercurial agents excite the liver and it pours out its morbid product; or, if they aggravate the existing hepatic derangement the green may be increased by this vital influence of the agents, or the secretion of bile may be wholly arrested.

It is important to do away with these misapprehensions; since they lead us to regard what is truly an important symptom of disease as the mere result of accident. The experiments, also, out of the bedy

show us how fallacious are all such pursuits (§ 1058 b).

The worst appearance of the bile, per sc, whether vomited or dejected, is a bluish color. It shows severe and obstinate congestion of the liver. Bloody mucus denotes more intense inflammation of the intestinal mucous tissue than a redundancy of simple mucus (§ 693). It shows dysentery if attended with pain and tenesmus. Hemorrhage from the bowels or stomach denotes venous congestion and then in congestive fevers the hemorrhage comes from the liver. In all the cases it is an effort of nature to relieve a very formidable condition of disease (§ 805. Also, Med. and Phys. Comm., vol. i., p. 371–384; vol. ii., p. 546–566).

4th. Of the sensations produced by the fecal discharges on passing the anus.—These are mostly of a burning or excoriating nature and denote either the presence of a morbid condition of the bile, or of acids that are generated by the decomposition of food. The suffer-

ing, however, generally arises from an acrimony of the bile. Aloes will, doubtless, produce irritation of the anus in some degree; but, when consequent on the use of that medicine, it arises mostly from the bile which aloes is particularly instrumental in eliciting from the liver; while its sympathetic irritation of that organ will also increase the morbid acridity of the bile. The fact is practically important, as will be readily seen from its bearing upon our conceptions of disease,

and of the virtues of remedial agents (§ 1063 b).

694½. From what has been now said, it is evident that the dejections should be always examined in all diseases of any severity and obstinacy; and, if produced by a cathartic, they should be all examined, and each one in the order in which it may take place. This is the only way of practicing medicine intelligibly. The evacuations often supply more information as to the state of the abdominal viscera than all other symptoms. I say, therefore, when cathartics operate, it is often important to examine the dejections in the order in which they may take place. The first may consist only of the fæces resulting from food, and of secretions which had not assumed a morbid aspect. With this partial inquiry, as is often the case, we may conclude that all is right with the abdominal viscera, or that they are in a state to bear any violent remedies we may choose to exhibit for other purposes. But, on inspecting the second dejection, we may find it like chopped grass, or of a black, pitchy aspect. This brings us to the conclusion that mischief prevails at the fountain of life. What was evacuated at this second discharge was perhaps nearly the whole contents of the intestinal canal; and what may be evacuated at the third, or fourth, or farther dejections, will have been secreted after each successive evacuation.

If any salutary changes, then, be exerted by the continued operation of cathartics, we shall be likely to discover them in the color and other appearances of the discharges, as they come away one after another. If they remain without change more work is to be done.

 $694\frac{3}{4}$. It appears, therefore, that modifications of mucus, wheresoever it occurs, and of the component parts of the alvine discharges, are essentially different from the morbid phenomena attending the pulse, the tongue, and the urine, as indicative of the nature and force of disease. The first being the direct results of organs morbidly affected are critically significant of the pathological conditions (§ 741 b). The last three, when the organs are not the seats of absolute disease, are indirect media which denote the intensity and modifications of the nervous influence that may be reflected upon the organs by diseases of other parts. our ordinary investigations of symptoms, therefore, which relate to the tongue, the circulatory organs, and the kidneys, we are employed, however unconsciously, in estimating the relative conditions of reflected nervous influence, and by which we judge of the nature of the pathological conditions in which these influences originate; although in respect to the tongue its morbid phenomena may be more or less owing to continuous sympathy in affections of the alimentary mucous tissue ($\S498\ f$, 500 m, 526 a, 715-719). And yet this is the great field of Humoralism.

This analysis may serve the useful purpose of drawing attention, for the first time, to the philosophy of the subject, and thus contribute toward an understanding of the same philosophy as it respects diseases which grow out of each other, and the operation of morbific and reme-

dial agents (§ 826 cc, 961 a, 970 c).

PATHOLOGICAL INDICATIONS FROM MORBID ANATOMY.

695. Lesions of organization, and all deviations from natural conditions which occur during life and are obvious to the senses after death, are embraced under the denomination of morbid anatomy.

696. All the foregoing results are owing to the pathological states which essentially constitute disease, and would not, therefore, ensue, could disease be removed soon after its invasion, or in its formative stage (§ 639, &c.). It is a great object of art to prevent their occurrence, or, as it is termed in the treatment of inflammation, to effect a resolution of disease.

697. Morbid anatomy has been pursued with various opinions as to its relative value to the vital signs of disease. Those who have regarded it of paramount importance have entertained but very limited views in physiology, or of the laws of disease. They have always considered the organ which was most frequently altered in its condition as the great primary seat of disease, and the cause of all the other lesions and phenomena, and even the cause of death. This docrine, and its fallacies, I have considered very extensively in an Essay on the writings of Louis, and in another article devoted specifically to the inquiry; both of which appear in the Medical and Physiological Commentaries.

698. Morbid anatomy is indebted to Bichat for its rank in science, by whom it was cultivated in its most philosophical aspects. It was this great man who first employed it, extensively, in illustrating physiological and pathological problems; but more especially did he convert the living phenomena of disease to the uses of physiology.

The fruits which were thus gathered from morbid anatomy appeared to represent the field as a terra incognita, where great discoveries were to be made, and, therefore, great fame to be realized. The older pathologists were either unknown, or crowded aside; while the very ground which they had gone over was brought forward as newly-discovered land. The multitude lost sight of disease in its vital as pects, and undertook a system of pathology out of the last wrecks of disease; not unfrequently confounding the results of putrefaction with those of vital actions. Such was the general state of this branch of science, upon which, also, humoralism had again reared its venerable form, along with many other physical and chemical doctrines, when I undertook their systematic examination. Nor do I say this in a spirit of arrogance, but as simply due to the philosophy which I have endeavored to defend.—See Rights of Authors, p. 912.

699, a. There has constantly been, however, a group of medical philosophers who have remained true to nature; and the profession, therefore, split into two classes, taking the names of the Hippocratic and the Necroscopic or Anatomical schools. The Hippocratists are observers of Nature in all her aspects; while the Necroscopists only contemplate her ruins.

699, b. The Hippocratists maintain that Nature is most significant of her existing conditions while those conditions actually exist, and

that we may better infer the nature of present causes by their immediate effects, than by the effects of other causes which may happen a

week, or a month, or a year afterward.

699, c. The Necroscopic or Anatomical school maintain exactly the reverse of the foregoing. If, for example, a case of inflammation of the lungs occur, they allow no satisfactory conclusions as to the nature of the disease till the patient is dead, and it can be seen whether there be certain morbid changes of structure, or certain physical products, which they assume as necessary to constitute inflammation. "In this country," says the British and Foreign Medical Review, "few would be disposed to admit that inflammation had existed, unless some of its known products were brought forward as proofs." If, therefore, a patient die of inflammation in its formative stage, and before any of its peculiar products take place, it is contended that there was no inflammation, however violent and characteristic may have been the vital signs. Hence it is assumed that the cause of death, in cases of. that nature, is wholly unknown (§ 748), or, "they are like inflammation, yet totally different" (§ 1024 d). The London Lancet has a more proximate philosophy. Thus: "Inflammation consists in this, namely, that the fibrin, &c., which should pass from the arterial into the lymphatic system, [!] passes into the venous. The true nature of inflammation lies in the above few words" (April 8, 1843).

A few of the most eminent of the Necroscopic school have exploded inflammation as a disease. This is extensively true of Louis, and universally so of Magendie and Andral; the last of whom affirms that "it is like an old worn-out coin, which ought to be discarded from circulation" (§ 753). Of fever, he says, "The progress of science has induced me not to devote, as in the former edition, a special volume to fevers."-" Singular 'progress' that!" exclaims Cayol; "a few such steps, and medical science would be down at zero" (§ 740 b, 744). The distinguished Travers, in commenting upon the Anatomical school, especially its corruptions in France, remarks that, "out of the debris of the dead subject, however accurately inspected, examined, and arranged, to attempt a solution of the great problem of living actions, and to build upon such a foundation an edifice of pathology of self-support, is as injurious a fallacy, and scarcely less arrogant and absurd, than that of the Cartesian Philosophers, who undertook, out of the depth of their anatomical sagacity, to make a man."—Note F.

699, d. Again, in another case where there may have been a succession of inflammations in different organs, and, although one or more in the series shall have entirely subsided, but the real cause of all that followed, it is assumed by the Necroscopic school that the last in the series had been the cause of all the phenomena from the beginning of the complaint. Such, indeed, as well as the preceding doctrines (§ 699, c), is the natural result of that large school of materialism which pretends to discover in the structure of organs, even in their molecules, the various conditions of life, and all its diversified phenomena (§ 131).

700, a. Take any case, in the wide range of diseases, and ere its termination, it may present many new problems for the pathologist. It may have lost its original character, or its variations may consist of such modifications of a common pathological cause, that the cure shall require alternations of opposite remedies. Every pathological change

is ascertained through the direct phenomena, and is a far more difficult effort than the primary conditions. Morbid anatomy contributes nothing through all the intermediate changes; and what, therefore, is its positive benefit in any given case of disease at its invasion or termination if it supply us nothing throughout its progress ? The whole matter is settled before morbid anatomy can yield its light; and Nature would have been untrue to herself had she left her dependence

upon art to her own ruins.

700, b. The physical products of disease can, at best, only denote the nature of an antecedent functional action in which the essence of the disease consists, and which has more or less terminated in the particular part when the lesions of structure and morbid depositions have taken place (§ 732 b, 863). On the contrary, if disease consist in structural lesions, or other physical products, to what practical result does morbid anatomy conduct us, if it inculcate such a doctrine? Organic lesions, and often preternatural formations, are to the physician what they are to nature,—ulterior results; and they are equally unacceptable to both. If the positive symptoms of inflammation are to be set aside from want of some of its terminations, or even of vascularity, the foundation of practical medicine will be swept away, and clinical lectures should be confined to the dissecting-room (§ 730 732 b).

701. Morbid anatomy, as taught by the materialist school, has precluded all regard for those pathological conditions upon which the lesions of structure and physical products truly depend, and about which the art of medicine is mainly interested. In its indiscriminate career, indeed, it cuts off all diseases except such as are known to the vitalist under the name of inflammation, and to which he refers those lesions of organic action and those new formations which alone engage the school of materialism. But the vitalist believes that "it is a rule of no small moment, in acute diseases," as expressed by Senac, "that there may be great disorder in the functions of the body without real inflammation, or any fixed disease in the solid parts. Yet these parts, which have experienced such deep and distressing affections, may, in a short time, be entirely relieved." "At the termination of a paroxysm of malignant fever, the terrible symptoms abate, and oftentimes disappear."

702. Morbid anatomy has not, in an original sense, ever given us a solitary clew to the pathology of disease, any more than healthy anatomy to the natural organic functions. We revert, at last, to the vital indications, or other immediate results, for this knowledge. The local symptoms are often an unerring guide, and many which spring from reflex nervous actions, where morbid anatomy professes nothing, yield also their flood of light. We analyze the whole group of phenomena, and, by the aid of experience and principles, we go to the work of cure without a doubt or hesitation. There is no other mode of practicing medicine. Or, suppose the anatomist to attempt a therapeutical application of his own materialism, physiological and pathological; could be even begin to consider the condition of disease, or the nature of its treatment ($\sqrt{500} \, m$, $514 \, f$ -m, $647 \, \frac{1}{2}$, $694 \, \frac{1}{2}$, $904 \, a$, $990 \, \frac{1}{2} \, a$)?

703. The legitimate objects of morbid anatomy are to expound the sensible changes which may take place in the instruments of morbid action, the lesions of structure, and other new formations, which may supervene upon disease. These it associates with what had been determined by the phenomena during life as to the essential pathological conditions; and, when doubtful cases may arise, from the absence of symptoms, should the physical results occur which have been found to be the regular sequelæ of certain known pathological states, it is then that morbid anatomy reflects its posthumous light with various degrees of importance. Yet certain it is that morbid anatomy can be of no advantage, so long as the symptoms, the true indices of disease, may be absent in any subsequent cases of the same nature, till the patient is again subjected to the scrutiny of the scalpel.

All physical results stand as the ultimate signs that a certain mode of action had existed, since these are the consequences of that action, of which the vital signs had been the attendants, and which had formed the sole ground of that pathological induction, which, after a series of observations, the physical products illustrate, and are taken merely as an indication that these vital signs, the basis of pathological induc-

tions, had been present.

704. It is manifest, therefore, that the materialism inculcated by morbid anatomy destroys all rational attempts at pathological inductions during the treatment of disease; since, if the true import of the vital signs depend upon the ultimate contingency supposed, no just conclusions can be formed, either as to the nature of disease, or the mode of treatment, till the patient is dead. This, it will be allowed, is repugnant to reason; from which it will follow that the premises are wrong, and that true pathology reposes upon the vital emanations of disease (§ 756, b).—Note F p. 1114.

705, a. It is, then, upon the symptoms of disease, its remote causes, and the effects of remedies, that we are to depend in reaching all practical knowledge of any individual case, and, therefore, all cases of disease. But, since the physical products of disease which are comprised under morbid anatomy are the results of the same properties and actions upon which the vital phenomena depend, they form an ultimate and subordinate source of information; and since they concur, more or less, with the primary remote causes of disease in ultimately modifying the phenomena, it is important to know, as far

as may be, the extent of their influence in this respect.

705, b. I may say, therefore, that the greatest practical use of morbid anatomy is the knowledge it supplies of the tendency of certain pathological conditions to result in the formation of physical products, or in disorganization; thus giving that direction and energy to practice that may be necessary to counteract the supervention of these deplorable consequences of disease. A second important practical advantage is the discrimination which morbid anatomy enables us to make between those phenomena which are the result of simple morbid conditions, and such as depend upon, or are modified by, the supervention of physical products.

706. Morbid anatomy can never alter the general principles which it may have assisted in forming. When, for example, the nature of common inflammation is ascertained in one part, principles are established which are applicable to this disease in all other parts, and at all times, and under all circumstances. The varieties must be ascertained by interrogating the particular phenomena in each individual case, and the treatment adapted accordingly. The great principles

will, of course, be always under the modifying influence of the phenomena from which they have been deduced, according as the princi-

pal phenomena may fluctuate.

707. When the structure of parts becomes deranged, or the properties of life are verging toward an extinction, we have totally a new order of things. Pathological principles are then upon the decline, and therapeutics is more or less afloat, and without compass, on the broad ocean of experiment. The organic being is fundamentally changed in his structure, and the laws by which he is naturally governed are more or less broken up. And I may also add, without intending to discourage its legitimate pursuit, that here it is that morbid anatomy begins, and has reared its pathological fabric on the ruins of organization.

708. Whenever morbid anatomy has been in the ascendant, the practice of medicine has been either experimental and empyrical, or has run into a mere system of "watching," or what was anciently denominated "a meditation upon death." We need only turn to the present state of medicine in the Capital of France for a melancholy exemplification of what I now state, and which I have set forth ex-

tensively in my Essay on the Writings of Louis.

709. The foregoing section leads me to a review of the past, and to inquire how far events have justified my former conclusions as to the superiority of American practice, and of American medical education, over European, as expressed in my Essay on the Comparative Merits of the Hippocratic and Anatomical Schools. I had deprecated more especially the corruptions of French medical philosophy, and was led to remark, that, "already our young men are crowding the schools of the French Metropolis in pursuit of a more thorough knowledge of morbid anatomy; and immuring themselves within the walls of Parisian hospitals, to contemplate the worst ravages of disease upon subjects of broken-down constitutions, and who have passed the ordeal of French hospital practice. They return home with Gallic pathology, and the results of Gallic therapeutics, which they could not realize in their own country, and will never witness again but by carrying out the principles which have supplied them with their means of information."—Note W p. 1127.

It is true that a few have been not a little employed in disseminating these corruptions in this stable land of sound medical philosophy; but, nevertheless, I am still able to repeat, that, "What Americans have received from the devotees of Morbid Anatomy, or from such as would make Chemistry the basis of organic science, has only tended to show them more distinctly, that the phenomena of life, in their various relations, are the true foundation of principles in med-

icine" ($\S 350-350\frac{3}{4}, 744, 821, 830$).

And now, having obtained the requisite permission from one venerable in years, profound in science, and long eminent as an expounder and teacher of medicine, and practically familiar with European habits, I shall here subjoin an extract from a letter which he did me the honor of addressing to myself, from Louisville, Ky., April 5th, 1846.* I am immediately prompted to this step by the

^{*} In alluding to my Defense of the Medical Profession of the United States, Professor Caldwell goes on to remark that,
"On perhaps every part of your unsparing career throughout your task, from begin

manner in which the Medical Profession of the United States has been lately presented to the World by the Medical Society of the State of New York, in the hope that I may be thus instrumental in

ning to end, my sentiments accompany you, and probably on one, at least, leave you a little in the rear. I allude to the practical superiority which the physicians of our own country hold, in general, over those of Europe, and I presume also, of course, of every

other portion of the globe.

"Respecting the treatment of chronic complaints I forbear to speak; because my knowledge on that point is less full and thorough, and therefore my opinion less positive. But, in their rational, skillful, bold, and successful treatment of acute diseases, particularly of the classes febres and phlegmasia, the physicians of the United States are incomparably superior to any Europeans whose practice I have either witnessed in person, or read of in books. That this is true in relation to American complaints cannot be denied. Nor, in my opinion, is it less true in respect to those of transatlantic countries.

"Of all the physicians in Europe of whom I have any knowledge to be relied upon, I

am most partial to the practice of certain Dublin gentlemen, and of those in some parts of Italy. In their treatment of disease they have often reminded me of home. And of all the practice I have ever witnessed, that of Paris is the most inefficient and miserable. Yet is it this Parisian school in which American pupils are most anxious and proud to be educated, and to which they are advised to repair; and most unwisely and inconsiderately advised. As far as the practice of medicine is concerned, if they do not there learn how to kill the sick themselves, they learn, or may learn, to perfection, the art of allowing their complaints to kill them. Never have I witnessed in Paris a single well-directed Herculean blow attempted in a case of fever. The battle was always fought in a Lilliputian manner. Nor, were I to say the same in relation to English and Scotch practice, would it be easy to refute the assertion. It is a well-known truth, that European physicians of every nation, who migrate to America, are, on their first removal, incompetent to the successful treatment of the complaints of the country; nor can any thing but experience render them competent to it.

"It is undeniable, that the physicians of Europe are, in the mass, very far from being an able and elevated body of men. Strike off the few, I might say the comparatively very few, who alone give lustre and standing to the profession, and the remaining 'million' will be found to be positively and strikingly the reverse; a very ordinary body, possessing not an element of distinction on the ground of either talent or attainments. And the same is true in relation to the pupils whom I have seen in attendance on the Euro pean schools. A majority of them, which may be called vast, are, in appearance, far inferior to the pupils of our own schools. Nor have I the least reason to believe them much if any less, inferior in *mind* than they are in *person*. In proof of this, the American pupils, whom I have seen in attendance on foreign schools of medicine, were, in no ordinary degree, the finest young men belonging to the classes; the foremost, I mean, in every essential attribute of standing. Of this they were themselves confident and proud; and so

"It is not true, then, that the mass of physicians in Europe are, in any respect, superior to the mass in the United States. In their treatment of disease, I fearlessly repeat that they are decidedly inferior. On each side of the Atlantic, the west not less than the east, there exist in the Faculty the eminent few, who, in talents and knowledge, are nearly on a par; the Americaus, however, being at once the most efficient, most rational, and most successful practitioners.

"While I yield to no one, therefore, in the estimate I place on the leading physicians of Europe, I cannot admit that those of the United States are in any respect their inferiors. And I should deem myself unworthy my birth-right, were I not to discountenance the wordy tirade poured out so superabundantly in certain quarters, in disparagement of the education and standing of the great body of American physicians.

"For the inferiority of the mass of European physicians a plain and substantial reason may be assigned: they are enslaved by precedent and trammeled in mind, and are not, therefore, independent thinkers. And I need hardly add, where independence of thought is wanting, so are vigor and efficacy of thought."

"An overwhelming majority of the physicians of Europe reside and practice in country

places, villages, and small towns. And, as already alleged, they are, ab origine, more or less of an interior caste. Their education is also inferior. Hence, conscious of their inferiorless of an inferior caste. Their education is also inferior. Hence, conscious of their inferiority, they look upward for light and direction, and follow those whom they acknowledge as their superiors. In this they but conform to the European fashion, according to which the lower orders of society do a sort of homage to the higher, and walk in their footsteps. So lower orders of society do a sort of homage to the higher, and walk in their lootsteps. So true is all this that there are few, if any, medical commoners in the Old World, who venture to think in any other way than by authority of some writer or teacher; whom they obey and adhere to as retainers do to their feudal lords. I need hardly subjoin, that in a condition so humiliating, it is impossible for physicians to rise to eminence.

"Much of this, however, you have yourself stated in your 'Defense of the Profession,' or elsewhere. But I am not apprized of your having stated that the American youth can be much better educated in their own country, than in any foreign one. Yet is the fact re-

much better educated in their own country than in any foreign one. Yet is the fact unquestionably true. I mean that it is a fact, and not a narrow-minded, selfish assertion. The real proximate elements of medicine are more thoroughly taught in some American

obliterating unmerited reproach, and in inspiring my medical coun trymen with that consciousness of worth, and self-respect, and selfdependence, which they are so eminently entitled to enjoy.

schools, than in any European ones I have ever visited. This is especially true in relation to the Principles or Philosophy of medicine; without an acquaintance with which the practice of the profession is rank quackery."

I have no disposition to pursue the foregoing subject beyond what may seem expedient for the defensive purposes which common justice urges upon an injured right. The scope of ramark is therefore designed to extend far beyond those domestic relations which might be adjusted without foreign aid. But our own self-reproach was not the offspring of conscious degradation. It was but the sequel of disdain which prospective greatness never fails to encounter on its triumphant march. The aspersions of the mother-country had been received in the dignity of silence, and they who undertook the game at home calculated to win through an imaginary acquiescence in foreign diplomacy and an accustomed non-resistance. All that was noble in our land had been the subject of unmitigated scorn; and so it progressed under the blandishments of diplomatic skill. I will not point, in testimony of this, to the "London Quarterly," or political, or other journals of inferior note; but that which has reigned supreme in the world of letters unfolds an amount of proof at which Honor and Humanity hang their heads in shame. The blows have not fallen upon the imbecile and weak. That is the coward's work, and would have yielded nothing to the final cause. A nation has been the intended victim, and therefore a nation's pride for the defensive purposes which common justice urges upon an injured right. The scope the final cause. A nation has been the intended victim, and therefore a nation's pride has been the target. The critique upon Channing in that National work, the *Edinburgh Review*, for April, 1839, is alone enough to dishonor any country, at any age.

I shall, therefore, briefly sustain the foregoing comparative estimate of the Medical Profession, in a limited application to "the Mother-Country." I complain not of any other; and revere the ancestor as a fading luminary, of the largest magnitude, whose resplendent light has only passed into other regions to advance the welfare of other worlds. I shall sustain the comparison, I say, by a quotation of one of many analogous comments that have lately appeared in a medical work which may be regarded as the oracle of the British Profession,—the LONDON LANCET.—NOTE W p. 1127.

In speaking of the existing state of medicine in Great Britain, and after representing

British "works on pathology and the practice of medicine as deficient in originality and richness of materials," the veteran editor aims his Lancet at the very foundation. "Look," he says, "at the state of British pathology! Of what does the great majority of our books on this subject consist? Of compilations; of old views cooked up as new discoveries; of annotated translations; or, at best, of able and comprehensive digests of materials that were already before the public in other forms."—London Lancet, May 6, 1843. And may I not adduce, in support of the Lancet, what I have said in former sections of the reference and surrender of British medicine to the laboratory of a German chemist (§ 349, d, 3762, 676, 878) ?1

Shall Americans, therefore, go on to decry the efforts of their own medical scholars, degrade the whole profession of their own country, and sacrifice their own medical literature for what is conceded to be the present medical literature of Great Britain? It is not mine to complain of British critics for promulgating what could not be concealed; and, doubtless, it is the only remedy for professional apathy, the only stimulus to "medical reform," the only motive for "Parliamentary action," and the only means of extending education and of rescuing the practice of medicine from the hands of "apothecaries."

There has been no occasion for vindictive motive; which never fails to tarnish truth or polish error. The common ends of life are known to all, and each in his place, in the scale of conscience, weighs, to the weight of a thought, the right and the wrong. once true is true forever; and nothing has stood the test of truth like the great elements of national decline. In vain do we point to our former greatness, and call for help upon the past. The very power of example is gone. What was noble, was virtuous, was intellectual has passed to other regions, is cherished and honored in other climes. It is

lost only to the land of its birth.

While, therefore, we adopt whatever is valuable from abroad, let us have a literature of our own, based upon American observation, American industry, and American genius. of our own, based upon American observation, American industry, and American genius. But, as I formerly said, let us remember the admonitions of history, that, when nations have begun to trample upon the past, to reject its experience, and to strike out new systems of observing Nature, it has been the most certain presage of approaching imbecility, and of that ultimate fall to which all are destined. When the great revolution shall have reached the Genius of Philosophy—"το κρατίστου της φίλοσοφίας"—the last vial of wrath is emptied, and that nation is irretrievably gone. This is humiliating to pride, and may have been designed as one of its correctives. But since it is so in the great plan of Providence, it must be sufficiently obvious, that, as a nation approaches its chaotic state, those who may be in the ascendant are bound neither to counteract the order of nature, nor to sufhay be in the accentant are bound in the bound of the bou erects its innovations upon error, and imbues them with superstition and absurdities.

I say, therefore, let us have, at least, a medical literature of our own. There is nothing that will contribute like it to the nationality of Americans, nothing that will inspire so extensively the culture of other sciences, promote the advancement and refinement of the

¹ The LONDON LANCET will concede that all things remain in statu quo, 1860 .- Vide Note, p. 517.

Other, and perhaps I should say more important objects, are contemplated by this note, and which form no small part of the interests of medicine. They are the same which I have had uninterruptedly in view. They are those which are intended to designate the consequences of spurious systems. Those systems and their results must be displayed; and that, too, in connection with what may be designed as substitutes. Nor is there any inquiry in which this method is so indispensable as in the philosophy of medicine. Truth would never obtain, till the "lion shall lay down with the lamb," unless the Institutes of Organic Nature are presented in forcible contrast with the devices of art. It has been tried from the day when Hippocrates evolved the philosophy of medicine from Nature herself, and dragged it from the midst of error and superstition. It has been tried, I say, in vain. The present times bear me witness of the fact. The mind must enjoy ready means of comparison. Nay, more, the comparisons must be planned, matured, logical, and irresistible. Such, only, can give stability to medicine; can, only, illustrate and enforce the truth. I have made the attempt: I do but say a humble attempt. I design it as an example for more able pens; and ever consistent and firm in the views which I have now expressed, I would cheerfully become, upon my own method, the victim of a better philosophy. I would have corruptions, speculations of all kind, swept with an unsparing hand from the tablet of organic nature; and while, therefore, whatever I may have attempted shall remain unrefuted, uninvalidated, or however it may receive approval, or be condemned without "the ordinary prerogative of being presumed to be true until the contrary is clearly shown" (§ 3763, a), I shall suffer the method of inquiry to remain undisturbed, the exposures of error to hold firm their places, in any future editions of this work; that they may unceasingly contribute to their original objects, and admonish the pretender, that some one more competent to the task may fasten upon him a universal verdict of guilt. They will therefore remain, as a safeguard to medicine, till the corruptions be shown to bear on their front the broad seal of Nature.*

useful and ornamental arts, nothing that will so effectually confirm and carry forward that elevated rank which the Medical Profession of the United States have already won for themselves in the hearts of their countrymen. We have, indeed, already the foundation of such a literature in the multifarious writings of the hard-thinking men of America; and it is this very literature, and the general dissemination of knowledge in the American Medical Profession, their indomitable industry, their well-directed skill, and their discreet and dignified bearing, which give them higher rank, greater influence in society, than any other class. Look where we may, we shall be likely to find the medical man foremost in enterprise, turning night into day, leading in measures for the public health and for its general prosperity, curbing the impetuosity of error and superstition, rearing and consecrating temples to the Divinities of Health wherever a dozen worshipers can be found, and stretching out an influence which awakens all the elements of learning and industry.

It is the Profession alone which is not true to itself.

In all that I have now said, I may not be suspected of undue partialities, for I am un-In all that I have now said, I may not be suspected of undue partialities, for I am under no obligation to any portion of my profession in America, or of the American Republic; while I am actuated by the deepest sense of gratitude to some foreign countries that can be inspired in a man of literary habits. To those countries I am the more indebted as they are always just to my native land, do honor to her scholars, and are the great abodes of learning and philosophy. Nevertheless, in all the instances I have endeavored to speak according to my convictions of the truth, and the demands of my subjects; ever sacrificing self to those primary objects. If there may seem to have been asperity, I trust it will be found in the facts themselves, and in the unavoidable nature of the conclusions at which I have arrived.

clusions at which I have arrived.

^{*} The subject of Medical Education, and the great superiority of the system pursued in the United States over that of Great Britain, was resumed in a series of seventeen numbers, which I contributed (but which appeared editorially) to the New York Medical Press (from Jan. 29th to June 4th, 1859), founded upon Parliamentary doc'ts.

INFLAMMATION AND FEVER.

710, a. I PROCEED to illustrate the most important principles in medicine by considering those which are especially relative to inflammation and fever; the two orders of disease, indeed, which make up the great amount of human maladies, and form the great outlets of life. The few diseases which do not fall under one or the other of the foregoing denominations are least important in a practical sense, and least understood in their pathology. Nevertheless, a knowledge of the principles which apply to the pathology of inflammation and fever will greatly aid our interpretation of the essential changes which constitute the pathological conditions of other affections.

710, b. Inflammation and fever have been generally regarded as one disease, and they who have considered them distinct affections have offered no analysis by which their individuality may be established, and by which each complaint may be readily distinguished in practice. Important evils to the sick are therefore in constant progress from this source alone; and when there is added to it the entire darkness in which venous congestion has been shrouded, both in its absolute pathology and as it modifies fever and the recognized forms of inflammation, it may be safely said that a vast opening is here presented for the improvement of medical philosophy, and for the common welfare of man (§ 787, RIGHTS OF AUTHORS, p. 919, nos. 27, 28).

INFLAMMATION.

711. I shall first state the outlines of inflammation, and its essential pathological characters; from which it will be seen that it takes its rise in purely physiological conditions, and holds its progress and decline under the same great natural laws of the constitution (§ 137, 149-152, 638).

712. Unlike idiopathic fever, which is a universal disease of the body, inflammation is always local (§ 143, 148). Fever, however, is often complicated with inflammation of one or more organs at or near its commencement, and the local disease may precede the constitutional one, and even become the exciting, though not the predisposing, cause of it (§ 645, 650, 651, 653). More frequently, however, inflammations spring up during the progress of idiopathic fever, and often attack and disorganize many important parts in rapid succession. Indeed, it is rare that fever exists long without this greater foe making its appearance, and adding seriously to the difficulties and dangers of the case (§ 779).

713. Owing to the foregoing complications the capital mistake is often made of regarding the local affection as the essential or predisposing cause of the constitutional fever. Such pathologists assume, of course, that there is no distinction between fever and inflammation, and that both, therefore, are equally and always local diseases. But this is not the doctrine of those who depend less on morbid anatomy, and study Nature in her living aspects (§ 699). The single symptom which has given to fever its name has been a main cause of the confusion which prevails upon this subject (§ 657 b, 764, &c.).

714. Inflammations of much activity generally disturb, but very variously, the functions of many distant organs; but the results from their reflected nervous actions have mostly a different pathological condition from the primary disease, and such as are truly inflammatory are limited to a few parts; while all parts are affected in fever, and with pathological conditions more or less alike.

In chronic inflammations sympathies are more slowly and less extensively produced, or not at all where more acute forms would occasion great constitutional disturbance; even when the brain or other important organs may be the seat of the chronic variety (§ 140).

Acute inflammation, on the other hand, is prone to give rise, at its early stage, to what is called febrile action, or fever (§ 134, 139, 140, 150). But this kind of "fever" is purely sympathetic, never precedes the local affection, and is mostly remarkable for a simple ex citement of the heart and arteries; while in idiopathic fever, the most violent excitement often takes place without any appreciable antecedent local complaint, but simultaneously with the general excitement all the organs appear to have become involved in a morbid process; and now, also, inflammation may as suddenly supervene (§ 143 b, 148). The febrile condition proves an exciting cause of the other mode of disease in some part predisposed to the inflammatory process (§ $475\frac{1}{2}$ – $488\frac{1}{2}$, 500 m, $51\hat{4}$ f, 674 d, 903, 904 a, $990\frac{1}{2}$).

It appears, therefore, that great confusion has prevailed upon this all-important subject, and that causes have been mistaken for effects. and effects for causes. The excitement of the heart and arteries attendant on inflammation appears to have engrossed attention, inquiry to have stopped short as to all other organs, and a comparison to have been alone made between the general arterial excitement of inflammation and that which is attendant on fever. In one affection the general excitement may be almost the only element of disease beyond the local cause; in the other it is only one of a great number of elements distributed throughout the body (§ 487 h, 500 m, 686, $694\frac{3}{4}$).

Again, it is fundamental with inflammation that the sympathetic development of general arterial excitement will subside as soon as the local inflammation, or primary cause, is removed; but, in fever the whole disease continues after the original cause is removed. The organs of circulation may be long subject to very high degrees of excitement, as often witnessed in the intermittent fever, without a shade of inflammation presenting itself during the progress of the disease. And how clear the characteristic distinction, that in intermittent fever the excitement disappears not only periodically, but according, also, to the type of the fever, while in inflammation it remains till the local cause is removed; when, also, the whole disease is at an end. But violent inflammations which coexist with intermittent fever may be entirely subdued, and yet the fever proceed uninterruptedly. Again, it is a common circumstance that all idiopathic fevers are introduced by a chill; while such is rarely the case with inflammations. The chill, too, and of great severity, may attend every paroxysm of a longcontinued intermittent. Other distinctions in § 720, 757, 759, 764 a. e, 770.

715. When inflammation gives rise to general arterial excitement it is in part by continuous, and in part by remote sympathy (§ 498-500). The latter is mostly concerned in developing the general results The nervous power being excited in the brain and spinal cord is re-

flected upon the heart and capillary blood-vessels of the whole system, That power, thus reflected, proves a stimulant to these organs, by which their action is increased, and otherwise modified (§ 188, 205 226, 480-485). Again, the same primary inflammation which thus calls up a general excitement of the circulatory system may be simultaneously producing inflammation of some other and distant part, through the same process of reflex nervous action. That second part may have been predisposed to inflammation by some external remote cause, and the nervous power determined upon it may then operate only as an exciting cause. If the part be not antecedently predisposed, then the nervous power may prove the predisposing as well as exciting cause, or there may be other predisposing causes co-operating with it (§ 143-150, 226, 484 b, no. 6, 645, 652). This second part, thus sympathetically influenced, then becomes the source of other reflex nervous actions; co-operating, in this way, with the primary inflammation, and increasing more and more the action of the heart and arteries at large, and developing inflammation in other parts, while, also, the general arterial excitement is a supplementary mechanical cause. The circles of sympathy now become very complex, and interwoven with each other (§ 148); and yet, through the same laws of reflex nervous action a blow may be simultaneously struck at the whole by one decisive impression from a single remedy. Bloodletting, for instance, will do it; but the operation of this remedy, although involving the agency of the nervous power, is different, in some respects, from that of any other agent. But, suppose it may be done by an active cathartic, combined with a nauseating dose of tartarized antimony. The pathological states of the various inflamed organs are every where nearly or considerably alike. A single remedy may, therefore, overthrow at once the whole complex condition of disease (§ 137 d, 143 c, d, $476\frac{1}{2}$ h, 479, 481 g, 484 b, no. 5, 514, 557 a, 929-934, 944 b, 970 c).—Note D p. 1114.

715½. So also the foregoing modus operandi of the nervous influence in inflammation is applicable to the predisposing influences of the remote causes of fever (§ 148), of hydrophobia, of the constitutional effects of mercury, antimony, &c., and of all agents, indeed, which transmit their influences to parts remote from the direct seat of their operation (§ 500, 535, &c., 657). It is all by reflex nervous action.

716. The general sympathetic excitement is supposed to often constitute a state of general inflammation. But this is an error; since inflammation is always confined to some limited part, the minute vessels of which, and not the larger arteries and heart, are the instruments of the disease (§ 407 b, 410, 411). The term inflammatory fever is also objectionable, as being significant of what has no existence. The term constitutional derangement is commonly employed to denote the sympathetic disturbances which inflammation may inflict upon parts remote from its own location. It is the same condition that goes under the denomination of fever when owing to the reflex nervous actions of inflammation. But, unlike idiopathic fever, per se, it embraces a variety of morbid conditions in different parts (694\frac{3}{4}).

717. Inflammation occurring in one part may induce the same disease in another, and this last in a third, &c., independently of the foregoing affection of the heart and arteries. It often happens, also, that some sympathetic derangement will disturb the system far more ex

tensively than the primary affection. The heart may be the only organ that may be disposed to sympathize with an inflammation of the skin; but, when the action of the former important organ becomes disturbed, though only its irritability be increased along with that of the general arcerial system, it may develop sympathetically, and by a mechanical impulse of blood, extensive derangements, perhaps inflammations, in other parts. And so, in the same vital sense, of the stomach, brain, &c., when one of those organs may sympathize with some distant inflammation (§ 139, 140, 525 c), by reflex nervous action.

718. The more active and extensive the inflammation, the more important the part affected, and the more irritable and disposed to sympathy the individual, the more readily, in a general sense, will constitutional effects ensue, and vice versa (§ 139, 140, 597 d, 600 b). Exceptions are seen in the pleura and the mucous tissue of the fauces. But only, in the latter case, under special circumstances; probably of primary abdominal disease, when the secondary affection, which is commonly erysipelatous, reacts, in its turn, sympathetically (§ 689, l). The special sympathies of tissues and compound organs have been already considered in a general sense (§ 525-529). As it respects inflammation, a predominance is seen among certain organs, as the skin and mucous tissue of the alimentary canal. But the principle is more readily comprehended by observing its operation among parts whose natural physiological connections are strongly pronounced, as in the principal organs subservient to the process of digestion (§ 129, i). The sympathetic results may not be inflammatory, or of the same nature as the primary disease; but the organs which thus cooperate in a special function are readily disturbed when any one part of the system is invaded by disease, and readily excite reflex nervous actions among each other, and throughout the body (§ 514 h, &c.). The general constitutional affection is, therefore, often more or less dependent on the habitual association of the action of different organs while in health, as well as upon the nature of their vital constitution and their special relations to other parts of the body (§ 129). Owing, also, to the special modifications of the vital states of associated organs, some of them sympathize more readily than others with each other, and extend their influences more readily and powerfully abroad (§ 133, &c.). Thus, the small intestine occasions sympathies more readily and forcibly than the large, and the stomach more readily than the liver, with each other. But these morbid sympathies are not mutual among the parts where they occur most readily, and the same is true of their natural sympathies. Thus, inflammation, or any affection, of the small intestine commonly produces more or less derangement of the stomach; but the same affection happening to the stomach will not equally disturb the small intestine. Gastric disease readily deranges the liver; but hepatic affections do not as readily affect the stomach. Such are plain cases of reflex nervous action.

It may be also well to remark, that were it not that one part naturally sympathizes with others, it would never sympathize with them under circumstances of disease; no more than in plants (§ 113-117, 129, 183-185, 224, 226, 349, 456-461½, 475½, 493 cc, 578 d).

719. Violent sympathetic disturbances which are especially relative to the nervous system often spring up from simple irritation of the nervos of a comparatively unimportant part, as convulsions from

teething, &c. These conditions have been confounded with absolute

inflammation of the nerves (§ 526 d).

720. We may, perhaps, reckon as the first among my radical distinctions between inflammation and fever the fact that the constitutional disturbances of the former grow out of direct or reflex nervous influences instituted and kept up by local disease, while in pure fever they are independent of local diseases, though equally brought about by alterative reflex nervous influences (\S 233 $\frac{4}{5}$, 475 $\frac{1}{2}$, 647 $\frac{1}{2}$, 715 $\frac{1}{2}$).

721, a. Inflammation is a very comprehensive genus; or, perhaps, it should be rather said, it is a species of disease which embraces a mul-

titude of varieties, forming a truly protean malady.

721, b. According to the varieties, it is divided into common and spe-

cific, whose details distinguish it very broadly from fever.

In its most simple form, as arising from mechanical injuries, or as manifested in pneumonia, pleurisy, catarrh, &c., it is distinguished as common inflammation (\S 652, c).

When the disease presents certain peculiarities that are not attendant on the common form, it is called *specific*; as in small-pox, scrofula, lues, gout, rheumatism, &c., and in all cases of animal and veg-

etable poisons (§ 650).

722, a. Between the foregoing characteristic examples of common and specific inflammation there is a vast range of gradations, which meet, as it were, together; so that it is evident no definite line exists, and that all the individuals belong to a common family. The very extremes are so much alike that they may be compared to twins, which we may mistake, one for the other, at a superficial glance, or may only know them apart by some peculiarities of mind or manner; but which peculiarities, again, have so many points of resemblance that the same general system of moral and physical discipline is adapted to each of the twins, with only some special modifications to

suit the peculiarities of each.

722, b. In a general sense, when inflammation is produced by a single cause it appears under the same modification or variety (§ 652). But when two or more predisposing causes concur in establishing the morbid change the modification thus induced will be determined more or less according to their combined virtues (§ 652). Thus, cold applied to the surface generally produces what is called common inflammation. But it will also act as a predisposing cause of acute rheumatism, which is a specific form of inflammation, and therefore possesses peculiarities which distinguish it from all other forms. Hence, in this affection other predisposing causes are concerned, the principal of which may be ingrafted upon the constitution, or if transitory, may have begun the foundation of disease in the organs of digestion (§ 659, 661).

722, c. Inflammation is also modified by the natural peculiarities of the vital properties in the different tissues, and the sympathetic influences it may exert will often depend, both as to kind and intensity, upon the nature of the tissue inflamed, and the general nature of the compound organ of which the tissue may form a component part. As to the modifications of the disease and the reflex nervous actions as affected by the nature of the tissue, good examples of difference occur in the comparative phenomena and sympathetic effects

of pleurisy and phlebitis (§ 150, 160-162, 807, 809, &c.)

As to the modifications of common or specific inflammation which grow out of the combined peculiarities of the vital properties of particular tissues and of the compound organ of which the inflamed tissue is a component part, we have numerous and striking examples; as in inflammations of the brain, stomach, liver, intestines, &c.

Again, the phenomena will be varied as inflammation may affect different parts of one and the same continuous tissue, according to the nature of the compound organs into which the different parts may enter. Examples of this occur in the pulmonary and intestinal mucous tissue wherever it contributes to variations of the general

structure (§ 135-140).

722, d. From all that has been now said, it is evident that those lesions which have been rejected from the general denomination of inflammation by Louis, Andral, Marshall Hall, &c., and arranged under the designations of hyperæmia, hypertrophy, lesions of nutrition, irritation from loss of blood, contra-inflammatory action, &c., but attended by many of the characteristic marks of inflammation, fall naturally within the range of this variable affection, (§ 725. Also, Med. and Phys. Comm., vol. ii., p. 314-331, 712-715, 760, &c.).

723, a. Inflammation is also divided into acute or active and chronic; the former being more violent than the latter, comparatively of short duration, and commonly distinguished by a greater variety of local

results, and far greater constitutional derangements.

723, b. The foregoing pathological states, being essentially alike, run into each other; so much so, indeed, that what has been chronic may suddenly become acute, and pass with great rapidity through the different stages. There is, therefore, no other foundation for this division than such as is here indicated.

724. I am now conducted to an analysis of this disease, and shall

consider it.

1. In its most simple condition, as affecting different tissues.

2. As affecting different parts of different structures.

3. The varieties of inflammation in respect to its general attributes.

4. The sympathies to which it may give rise.

5. The remote and pathological causes of inflammation. The first four problems will be considered connectedly.

725, a. In a general sense, inflammation is attended by redness, tumor, heat, and pain. They were once supposed to be essential phenomena; but either may be absent, particularly exalted heat and pain. Their presence or absence, intensity or mildness, may depend upon the nature of the morbific cause, the nature of the tissue, &c. (§ 651, 722). Thus, there is no redness from the bite of a musketoe, and there is intense itching instead of the exquisite pain occasioned by the sting of a bee. None will deny that the affection resulting from the latter cause is exquisitely inflammatory, and all must allow the near coincidence between the two affections. By this analogy we bring, also, the white nettle rash, the white gangrene, scirrous tumors, &c., under one general pathological condition (§ 722, d).

725, b. Again, for example, in respect to pain, much will depend upon the nature of the tissue affected, and upon the force and kind of inflammation. Inflammation of the serous membranes is attended with far greater pain than the mucous; in which last it is often absent. Simple pneumonia may exist to an alarming extent with little

or no pain. The serous tissue, also, possesses only colorless bloodvessels in its healthy state, but is apt to become more florid in its inflammations than the mucous. On the other hand, parts which have only a dormant state of sensibility, as the tendons, bones, ligaments, may become exquisitely painful when inflamed, and more so when inflammation is produced in the fibrous tissues by a lacerated than an incised wound. There are also peculiarities as to the skin (§ 652, c). It is also worth observing, as contributing to a knowledge of the properties and laws of life, that while common sensibility is liable to be exalted in inflammations, specific sensibility, as seeing tasting, feeling, is apt to be diminished, or impaired in a different way from common sensibility (§ 133–137, 193–204).

725, c. It would appear, therefore, that increase of sensibility is only a contingent result of inflammation. This property, too, is not directly concerned in the organic functions; and a part is quite liable to become inflamed when all its principal nervous connections with the brain and spinal cord are separated (§ 188, 193, 205, 489, 500 d, 746c).

726. There is generally more or less pulsation in the inflamed part, and in the larger arteries leading to it (§ 498, 516 d, 803). In all such cases the extreme capillary arteries, which are the immediate instruments of the disease, and which naturally carry little red blood, have become enlarged, and admit the red globules. This transmission, however, of the red globules is less due to the enlargement than to a change in the relation of the vital properties of the vessels to these globules (§ 192, 384, 394, 396, 398, 399).

728. Like the arteries, the veins of an inflamed part are increased in size; at least when the former are enlarged. This is owing to active dilatation of the veins, and to the increased volume of blood

transmitted to them (§ 387, 786, &c.).

729, a. Common inflammation, when it goes on to a natural termination, and in its greatest latitude of simple results, may be distinguished into four stages; namely, the formative, suppurative, ulcerative, and restorative or granulating. There may be present, therefore, from what has already been said, only the formative stage (§ 700, &c.). When the disease does not advance beyond that stage, it is said to terminate by resolution. The suppurative and restorative stages form the most simple natural process of cure. They are also subject to great irregularities.

Pathologists have generally reckoned the *adhesive* process as a distinct stage of inflammation. It will be seen, however, that it is not

founded on principle.

729, b. The curative stages of inflammation, whether regular or irregular, are also called terminations of inflammation. The term is significant of what has not truly happened; and, as words have often more force than facts, it should be abolished. There is great practical philosophy concerned about the mutations of disease at the several regular stages of inflammation, and in all the modifications to which those stages are liable. There is but one termination of disease, excepting death. Disease remains, however altered from the formative stage of inflammation, till nature is completely restored (§ 672, 733 c).

730. The formative stage is distinguished more or less by the char-

acteristics already described.

The suppurative stage is introduced by a decline of all the symptoms of the formative stage, and when most regular there is a production of purulent matter, which constantly tends to a more com-

plete removal of the formative stage.

The *ulcerative* stage is more or less attendant on the suppurative; generally attends the formation of pus excepting on exposed surfaces, when it may be present or absent (§ 733, b). Whenever present it is immediately antecedent to the restorative or granulating stage, although a destructive process.

The restorative or granulating stage is promoted by the suppurative, and is marked by a continued decline and ultimate disappear-

ance of all the symptoms.

731. The foregoing stages are generally more distinctly marked in the cellular than in other tissues. With the exception of the ulcerative, they may be often well observed upon the mucous tissue of the eye. The ulcerative is seen in the intestinal mucous membrane.

732, a. Deviations occur in the suppurative stage in the production of coagulable lymph, or of serum, or redundant mucus, or effusions of blood, instead of purulent matter. But these results, or however they may deviate from their proper standard, are all analogous to the formation of pus, being exactly equivalent in principle, constitute equally the second stage, and, in the same way, contribute to the restorative stage, or that of perfect cure (§ 732 f, 740 b, 764 e, 863 a).

732, b. The fluids effused operate as depleting means; and it is especially for this reason that morbid anatomists, not finding the vascularity they had anticipated, declare that its absence in many dropsical affections denotes an exactly opposite pathology from that where the same affections are attended by a preternatural fullness of the vessels (§ 699 c, 700 b). Nature, however, has no such inconsistencies (Med. and Phys. Comm., vol. i., p. 180–182; vol. ii., p. 187, 199, 556, 557, note). At the first reference here made I have quoted the mechanical rationale as propounded by Andral, and have endeavored to prove, by his own showing, that what are denominated "passive dropsies" depend on a vital, inflammatory action (§ 740 b, 805, 863 a).

732, c. When the second stage of inflammation is attended by an effusion of coagulable lymph it is called the *adhesive*, instead of the suppurative stage. This variety appears mostly in the serous and cellular tissues, though it is often presented by particular parts of the mucous system, as that of the trachea in croup, and of the intestines

(§ 133-135).

732, d. When wounds heal from the effusion of coagulable lymph, it is by the "first intention;" though the process is the same as when the pleuræ unite, or the lungs become hepatized in pneumonia. In either case the new formations are a part of the natural process of cure (§ 732 a, b, 863 a). However momentous the evil in pneumonia, or other disorganizations, it is still the result of the great recuperative law; just as effusions of blood within the head in cases of cerebral congestion are on a par with hæmoptysis, hæmatamesis, &c., or all dropsical effusions with each other, and with the preceding results. Nature makes no digression from great principles for minor purposes. But, in the apparent contradictions now stated Nature has duly provided for the removal of extraneous matter from shut cavities, and from the recesses of organization by the function of ab-

sorption (Med. and Phys. Comm., vol. i., p. 371-384; vol. ii., p. 546-

566, 733).

732, e. It is also a peculiarity of lymph not appertaining to pus that it is readily susceptible of organization, whereby Nature accomplishes other purposes; though such organization occurring in pneumonia is, as in § 732, d, an apparent though not a real departure from the great law of recuperation. Being a law of Nature for reparation in other parts, it must, under equal circumstances, prevail in all parts.

732, f. It appears, therefore, that the adhesive process consists of two stages; that by which lymph is effused, and the strictly adhesive. And, although the effusion of lymph be equivalent to the suppurative process, there is superadded to the former a distinct final cause, since Nature contemplates in this modification not only the curative effect,

but, also, the reparation of injured parts (§ 732, a).

733, a. When suppuration occurs upon surfaces, as on the mucous tissue, the process happens in its most simple form. But, in other instances, as when pus is generated by the cellular or serous tissue, the matter cannot escape as when it is produced by the mucous tissue. In these cases, therefore, an obstacle intervenes between Nature and the cure, as when the formation of lymph or of serum takes the place of purulent matter (§ 732, d). But here, as there, Nature has provided for the removal of the secondary evil, through a principle common to all the cases, and which appertains to the absorbent vessels. This happens after the following manner, which must be briefly stated as characterizing an important law, and the third stage of inflammation.

733, b. The process is called ulceration (§ 730). It consists in the absorption of all the tissues intervening between the accumulated matter and some external surface. It is so significant of a great final cause, so replete with evidences of Design, especially in connection with the other attendant processes, that some authors, even Hunter, have metaphorically ascribed it to something like intelligence. It is to be observed, also, that in this complex condition there is in simultaneous progress both the formation of pus and of lymph. The pus occupies the central parts of the abscess, while the lymph is effused at the circumference, agglutinates the cellular tissue, and thus, by forming a sac, prevents the spread of the purulent matter. It is yet another part of the complex law under consideration, that while the substance between the abscess and external surface is constantly yielding to the ulcerative process, reparation or the granulating process is going on posteriorly to the abscess, and the redundant lymph undergoing absorption, or what is equivalent to the ulcerative process in the anterior part of the abscess. There is, however, a certain difference between the processes; but it is less than between the absorption of lymph in the present example and the function which is in universal operation in health. In the case before us, like ulceration, the absorption of lymph is an emanation from inflammation, though more remote than ulceration. Both, therefore, may be regarded, though not equally, as pathological conditions of absorption (§ 672).

733, c. When the surface is reached, and the matter discharged, the cavity is no longer circumscribed. Nature now puts an end to the destructive process, and completes the work of reparation which had been in progress in the posterior part of the abscess. This is ac-

complished by the formation of a substance analogous to that which had been removed. Coagulable lymph, along with more or less purulent matter, is secreted by the surface of the ulcer, upon which it is arranged in little fleshy heaps, or knobs, of a florid color, and forms the granulations. These knobs contract and spring from the top of each other till the cavity is filled.

Among the various and striking results which are involved in this process of reparation none is more remarkable, or more strongly exemplifies its dependence on laws that are unknown in the inorganic world, than one which is least appreciated, the substitution for the granulations of an organized substance similar to that which had been removed. The granulations have, originally, the same apparent physical characteristics, from whatever part of the body they may spring. But they are so endowed with the special vital characteristics of the parts by which they are generated that in each part they secrete a substance which is similar to the part removed, while the granulations themselves are progressively absorbed (§ 135, b). Doubtless, also, the granulations are specifically different, in a physical sense, in all the cases, differently organized, and therefore, as in all other cases of organized lymph, derive their vessels from the parts by which they are generated (Med. and Physiolog. Comm., vol. ii., p. 354-362).*

The cavity being filled, the granulating process ceases, as if instinctively, and a new one sets in, by which the granulations are covered with a substance analogous to skin, and which is called the cicatrix. This completes the series of Designs attendant on the different stages of an abscess, and which exemplifies all the regular stages of inflam-

mation (§ 729, b).
733, d. Who shall resolve the foregoing wonderful processes and results, their exact concurrence, their obvious design, their great final cause, by any process or laws of the inorganic world? Yet is even this now almost universally attempted! Such is ever materialism! But, when it will not listen to the voice of Nature as it proclaims her Author, we may hope in vain for any interpretation of her phenomena that may recognize dignity or design in her minor aspects, and least of all as it may conflict with the fundamental principle of materialism. When error is bold in its demonstrations it is reckless of consistency, and therefore regardless of facts (§ 51, 52, 40, 80, 117, $137, 143, 155, 156, 169 f, 172 b, 226, 303 \frac{1}{4} a, 306, 310, 311, 350 \frac{3}{4} g-o,$ $376\frac{1}{2}$, 384, 385, 387, 399, 409 f, 422, 500 n, 514 h, 524 d, 525, 526 d, 528 c, 638, 649 d, 733 b, 764 b, 811, 847 c, 848, 902 f, 905, 943 c, 980, 1019 f, 1085).

733, e. As we have now and before seen, Nature often contemplates a variety of useful purposes in the individual processes she adopts for the benefit of organic beings. The healthy state of the body is full of examples. Every action of every part has commonly more than one definite object; often many. So is it, also, with those morbid processes which are instituted for the restoration of health. As soon as the tendency in diseased actions is set up toward the natural condition, the subsequent changes have a specific reference to the ultimate cure; the completion of which, however, may be very remote from the initiatory step. The vital properties and actions may pass through a variety of changes before they attain the natural physiological condition (§ 672, 676). But each change, each step in the

^{*} Ollier's production of bone by the transplantation of periosteum is a good illustration of thi subject.-1860

process, may be necessary to the next succeeding, till Nature attains her normal condition. This, however, is only one part of Nature's plan in her salutary efforts to escape from disease. She renders various results, as she goes along, instrumental in bringing about the subsequent steps in the process of cure, and even associates with these other useful objects. In the case but just before us, while ulceration is making its way to the surface for the discharge of matter, the purulent formation is constantly subduing the inflammation, and the secretion of lymph, which is designed for agglutination and granulation, has the same salutary influence upon the morbid process on which its production depends (§ 764, e).

The properties of life are thus constituted in such a manner as not only enables them to undergo changes from their diseased to healthy states, but, through their instruments of action, to result in the formation of products which shall contribute to this great ultimate end (§ 672, 733 d, 761). This is the philosophy of the vis medicatrix nature.

733, f. The foregoing law of reparation prevails universally in organic beings; extending, therefore, to the vegetable kingdom. It appears, however, under various modifications, even among the animal tribes. It is presented in its most simple form in the growth of divided polypi, the reproduction of the claws of lobsters, of the lizard's tail, &c., when it takes the name of regeneration. But, it is equally an act of regeneration when ulcerated parts are restored in their former organization by the granulating process. The difference consists alone in partial modifications of a common action (§ 733, b). In the regenerative and reparative processes of plants the difference is still greater; and such as reject analogy, or cannot discern its light, have argued that the differences depend upon essentially different laws. A previous inflammatory action, it is true, is necessary to reparation in the higher order of animals, but is not necessary to the fundamental law as it is concerned in the regeneration of entire parts in the lower animals, nor in the reparative process of plants. The properties of life are differently modified in each, and consequently the processes differ, though as intimately connected by analogies as the modifications of the simple physiological states (§ 185, 672, 688 ee, 733 e). Nor is the granulating process an inflammatory one, but only consequent on that pathological condition; while the simple production of lymph may be a direct emanation from inflammation, or only consequent on its decline, or on a near approximation to that mode of action. All the modifications, however, give rise to corresponding va-· rieties in the nature of the lymph, just as they do in that of purulent matter. They may offer to our inadequate vision the sameness of appearance that is presented by the pus of an abscess, or of a chancre, or of small-pox, or appear as identical as the granulations of every part. The last, indeed, are the things in question; and although their ultimate results supply an unerring test, it is only coincident with all the others, and even with that which is offered by the natural states of the different tissues (§ 22, 42, 48, 53 b, 133, 135 a, 409 e, 411, 739, 740).

By thus pursuing the inquiry, the various results will be found connected by close analogies, though the extremes may be stumbling blocks to the careless. The periodical regeneration of the stag's horn, where some of the most characteristic marks of inflammation

are present, forms an intermediate example. But the deer, in other respects, is as limited as man, or other animals of the same complex organization, as to the principle of reparation. In all such animals, the amputation of a limb, or the removal of any important organ, is never followed by a regeneration of the part. Such parts do not embrace, like the parts of a polypus, or of a plant, the organization that is necessary to constitute a whole. Nevertheless, the law obtains, even here, to a remarkable extent. If the middle of a bone be removed, it is regenerated. But there must be opposite surfaces, and the right action must be instituted in each surface, as when the opposite pleuræ unite. In the same way central portions of the muscles and nerves may be removed and regenerated; and the process by which this is accomplished is the granulating.—See p. 473, note.

733, g. This leads me to notice a fallacy of the physical philosophers, who have been led into the error, as in most other cases, from neglecting, if not altogether the vital properties, at least their natural modifications as they exist in vegetables, and in the different races of animals (§ 133-163, 185). With this neglect of fundamental principles, and a substitution of chemical and physical laws (§ $5\frac{1}{4}$, b), they have endeavored to array an argument against the Hunterian doctrine of the dependence of the union of wounds, by the first intention, upon inflammatory action, by identifying the process of reparation in vegetables with the union of incised wounds. Reparation in plants, say they, is not an inflammatory process, and, therefore, the effusion of lymph in the incised wounds of animals is not connected with inflammatory action; and they endeavor to fortify this reasoning by an appeal to the regenerating power of the polypus, the lobster, &c. well might we argue that vegetables, and polypi, should be subject to the same diseases as man or quadrupeds, or that all animals should live alike upon the same kinds of food (Med. and Physiolog. Comm., vol. 1., p. 696-698).

733, h. The same objectors, however, set aside, on other occasions, some of the plainest and most important analogies of nature. They maintain, for example, that the functions of nutrition, secretion, &c., are carried on in all animals mostly through the nervous system, but are compelled to take a very different ground for the same functions

in plants (§ 350, no. 18-20, 62, 63, &c.).

The nervous system, however, being superadded to animals, modifies greatly their common properties and functions of life, expounds, in part, the differences and special analogies in the foregoing processes of reparation, regeneration, &c.; and being a superaddition to animals, and a large, however unintelligible element in the doctrines of the physical philosophers of life, I formerly employed it as the ground of an analogical argument that the principle of life was originally superadded to animals after the creation of their structure.

733, i. Consider, also, the parallel which holds between the morbid growths that are induced by special injuries of the animal and vegetable organization. Take an example of the latter in the nest of the Cynips quercus folii; and how evident is it, from this simple fact alone, that both departments of the organic kingdom are endowed with the same organic properties and functions, alike liable to dis-

ease, and governed by analogous laws (§ 185, 191 a, 409).

All the foregoing may be farther illustrated by what I have said in

a former section of inflammation in its connection with child-bed

women, &c. (§ 688, ee).

733, k. It is certainly remarkable that such obvious analogies should strike different minds under such different aspects, and doubtless many will think it superfluous that misapprehensions of the foregoing nature should receive a formal refutation. But they are sustained by minds that have a powerful influence, and must be respected. It is so, indeed, with the delusions of imagination itself; and were not a certain degree of resistance opposed to animal magnetism, its votaries would trespass far upon the domain of physiology, and trample without remorse upon universal knowledge.

Irregularities of Inflammation.

734. The regular stages and results of common inflammation which have been now described are subject to various irregularities, which spring from innumerable causes, but especially from morbific influences propagated from the organs of digestion. A great variety of modifications are also attendant on the specific forms of the disease; when the special results are apt to be mostly due to the nature of the predisposing cause. At other times, and in numerous cases of common inflammation, certain effusions, such as coagulable lymph and serum, which are equivalent in principle to the suppurative stage, appear to be regular stages. But they so often run into each other, that it is more philosophical to regard suppuration as the elementary process.

735, a. Instead of the progressive stages of inflammation, the disease may terminate in resolution. This result is generally intended to embrace one of the common products, coagulable lymph; the name and mode of termination coming to us from the humoral pathology. But, according to the philosophy which I have endeavored to set forth, I reject both the "concoction of humors" and the effusion of lymph, and mean by the term resolution a simple restoration of the morbid properties and functions of an inflamed part to their natural state, without any other supervening result beyond the formative stage (§ 729, b).

It is a primary object of art to anticipate nature in her depletive course, and thus prevent inflammation from passing beyond its incipient stage. It is here that the advantages of art are strikingly illustrated; since unaided nature proceeds to the cure by effusions of

lymph, pus, serum, &c. (§ 732 d, 863).

735, b. Inflammation frequently advances in its formative stage without being circumscribed either by effusions of lymph, or by other causes, and it is then diffuse. This irregularity is apt to attend upon some tissues more than others, especially the venous, lymphatic, cutaneous, and serous. There are also certain striking facts relative to diffuse inflammation which go to illustrate important physiological laws. Thus, in erysipelas, it is apt to be symmetrical upon both sides of the face. In phlebitis, the inflammation is often limited to the divergence of a vein (§ 741, c). In small-pox and kine-pox, the inflammation extends only a certain distance around the pustules, though not limited by the adhesive process. And here we may notice one of the various demonstrations of a law expressed in § 149, in the manner in which the sinapis, cochlearia, rhus vernix, &c., produce diffuse in

flammation of the skin (§ 649, c). Each of all the cases, and thousands of parallel examples, each as a whole, or in its details, supply so many problems for the profound inquirer, reveal the apparent mysteries of life, and stamp their seal upon the doctrines I have taught (§ 133-163, 177-184, 188-192, 651-657, &c.).—Note T p. 1125.

736, a. Opposed to the termination of inflammation in resolution is that of mortification, which is the greatest irregularity of the disease. Mortification, also, like resolution, commonly happens in the formative stage. This result also takes place, in most instances, when that stage has reached a very high intensity. Exceptions, however, as to the force of the disease, occur in dry gangrene, in the gargene of old men, and in white gangrene (Med. and Physiolog. Comm., vol. ii., p. 319, &c.). Irregular effusions are more or less attendant on this mode of termination.

736, b. What is the cause of mortification? It can be only said of it, that there happens a profound alteration of the properties and actions of life which results in their extinction, and that this change is of a vital nature and not dependent on mechanical causes, as supposed by the physical theorists, unless the circulation be artificially interrupted, and as practiced by these theorists with a view to an interpretation of a natural process. But this mode of death is as easily comprehended as that from fever, or hydrocyanic acid, &c. (§ 54-56. Also

Med. and Physiolog. Comm., vol. ii., p. 171-173).

736, c. By what process is the dead removed from the living parts? Here, again, we have, from most physiologists, a mechanical rationale which shall be consistent with the more important steps in their philosophy of inflammation. The dead parts, say they, are removed by the impulse of the vis a tergo. But I apprehend the process to be exactly the same as that by which a thorn is removed from a living muscle, or a scab from an ulcer. Each is, in the same relative sense, a foreign body, and each brings into operation, for its own removal, the laws which are represented in section 733. The dead part, like the thorn, excites inflammation in the surrounding tissues, suppuration and ulceration set in, the absorbents carry off the portion of the living matter contiguous to the foreign bodies, and thus is their separation effected. The process of granulation completes the cure (Med. and Physiolog. Comm., vol. ii., p. 167-172). Or, turning to the analogy supplied by the vegetable kingdom, will it be surmised that the removal of the dead parts of plants depends upon the mechanical action of a vis a tergo?

737. Another irregularity of inflammation respects the period of its different stages, one or more of which may be accelerated or protracted beyond the ordinary time. This is often true of the *formative* and restorative; and since the formative may be long continued, and then result in resolution, we see the importance of holding morbid anatomy

subordinate to the vital signs of disease.

The restorative process varies, also, as to its course. Granulations sometimes fail of approximating a level with the skin, when the true cicatrix may fail of being formed, and in the place of it appears a scabby substance, or some other imperfect formation, and often readily liable to absorption. At other times the true cicatrix is suddenly removed, the granulations absorbed, and the ulcer reproduced.

738. Scirrus is another distinct irregularity of inflammation. Here

the action is modified in a very remarkable manner, and is obstinately retentive of that peculiar modification. It is so far analogous, however, to common inflammation, that some of its worst results are an effusion of coagulable lymph, and destructive ulceration. It has been lately denied by the physical theorists that scirrus is an imflammatory affection (Med. and Physiolog. Comm., vol. ii., p. 321-330).

739. The products of the second stage of inflammation, pus, lymph, or serum, are liable to deviations; denoting special modifications of the pathological conditions upon which they depend (§ 733, f). Besides the obvious and well-known variations from the proper pus of common inflammation, there are other varieties which neither sense nor chemical analysis can detect; as in small-pox, and lues. It presents, also, certain obscure peculiarities according to the nature of the tissue by which it is generated (§ 133-137); and this is also true of the morbid production of serum (Med. and Physiolog. Comm., vol. ii., p. 197, 198).

740, a. Every variety of product has its special pathological cause, which it is the great end of art to comprehend. It is the best obser-

vation ever made by Andral, that,

* We are not to suppose that the qualities of the purulent secretion are affected by causes which operate locally. The qualities are likewise modified by every alteration, whether physiological or pathological, which takes place in any other organ, no matter how far removed from the seat of the suppuration, even though it have no particular connection either of function or tissue. Thus, we have all seen instances of the pus secreted by the surface of a sore becoming suddenly altered in quantity and quality, under the influence of a simple moral emotion, of the process of digestion, of the diminution or increase, whether natural or artificial, of any of the secretions, or, in short, of any supervening disease. Nay, farther, there are certain constitutions, certain idiosyncrasies, which modify the qualities of pus, and in which it constantly assumes a peculiar and determinate character. There are some persons, for example, whose organs, when irritated, never furnish any other than a thin serous fluid; in others it is always blood more or less pure which is secreted; while in a third class of persons the place of pus is supplied by a grumous fluid," &c. (§ 134, 135, 222-232, 500, 585, &c., 593, 732, 733 f, 830, 847 d).

Thus have I quoted from Andral a luminous confirmation of my doctrines of vital action, of alterative nervous influence, direct and reflex; and I have adopted it on account of the force which it derives from emanating from a physical theorist of disease, and the dis-

tinguished restorer of the humoral pathology.

740, b. Nor have I yet quoted all from Andral that is expedient, in this place, on a subject where vitalism and solidism may establish their firm foundation; and this, too, by the most absolute, unguarded

concessions from the opposite school.

Let us hear, then, once more, the great modern humoralist. Thus:

"All attempts to modify the qualities of the suppuration by local treatment, in scorbutic and scrofulous subjects, are utterly ineffectual; for it is the system at large, and not merely the suppurating surface, which is deranged in nutrition and secretion. We must commence the treatment by endeavoring to modify the whole process of nutrition, innervation, and hæmatosis."—And again: "We do not know what

the peculiar modification is which the texture of an organ undergoes, so that in one case it allows the blood determined toward it to escape from its vessels; in another it forms pus, or exhales only a thin serum; while in a third, it becomes indurated, softened, and ulcerated; but there is a common link which unites these different alterations; and hence it is, under the influence of apparently the same cause, we often see them produced indifferently, and not unfrequently replaced one by the other (§ 732, a). But, in all this series of phenomena, we can perceive, throughout the whole course of the disease, one constant lesion, namely, the hyperæmia, and a succession of morbid alterations in the organic action of the tissue affected, producing, alternately, the results already mentioned" (§ 672, 733 e, f).

Here, then, are pure vitalism and solidism, because the writer was specifically concerned about matters of fact. The same principles, exactly, apply to all other actions and results which deviate from the natural condition of the body (§ 64, 345-350, $350\frac{3}{4}n$, 699 c).

741, a. Again, here is another important practical and philosophical fact, which distinctly evinces the dependence of all the foregoing conditions, changes, &c., upon purely vital actions. A suppurating surface may be so affected by constitutional influences, by disordered digestion, that the same results may follow as when the change is produced by some local irritant. This proves that the modifications of pus, and therefore pus itself, are not owing, as commonly maintained, either to a degeneration of the blood, or of the tissues, or even to changes of organization, but to certain modifications of the vital properties by which organization is animated; since it would be absurd to suppose that indigestion, and some caustic or other irritant applied

to the ulcer, would determine the same physical changes.

741, b. From what has been now and before seen, we may insist upon one of the most important conclusions in medical philosophy, which strikes at the whole foundation of humoralism, and is unsurpassed in its practical bearings. We may conclude, I say, that when serum, or lymph, or mucus, are diverted from their natural condition by disease, that the modification depends, in each instance, as much upon certain special physiological changes as do their natural states upon the natural condition of the solids. This analogy prevails throughout all other natural products of an organic nature, when turned from their common standard; and were there no other facts, the analogy would establish the same principle in relation to all new formations, as pus, &c. But, such facts I have multiplied abundantly in another work. All the varieties, every shade of difference, arise from modifications of action which are always necessary to the several varieties, respectively. The vital properties must be so modified in the several cases that the capillaries, acting in obedience to these properties, shall decompound, and recombine, the particular elements and constituents of each product, and in their proper ratio, and modes; rejecting all the rest. Otherwise, indeed, there could be no resemblances among the natural or morbid products, no gradations from one to the other, no obvious coincidence between certain morbid lesions of the solids and the resulting products. Every thing would be confused; there would be nothing but the riot of the chemical forces; and even empyricism would look on in dismay. The physical theorists, therefore, are forever involved in inconsistencies

excepting their universal collision with facts, and suiting hypotheses

to each particular occasion (§ 42-52, 409 d, $694\frac{3}{4}$).

But the properties of life can never undergo any change of their essential nature till they are verging toward a state of extinction. Hence the analogies among diseases, according to the nature of the remote causes. It is a great foundation of the healing art; and were it otherwise, medicine would be utterly fruitless, a mere creature of circumstance, one perpetual experiment (§ 638, 780).

The considerations which I have now made enforce, particularly, a critical reference to the pathological conditions in all our prescriptions, their seat, the influences which surround them, the precise adaptation of remedies as to their nature, dose, time and order of their exhibition, &c. They demonstrate, also, the distinction among remote causes of disease, especially such as have their origin in morbid or healthy processes of living beings, and establish the fact that the same disease cannot be produced by the products of organization

and of chemical decomposition (§ 653).

741, c. We may now glance at one or two important facts connected with the foregoing subjects. Thus, it is important to bear in mind that it is the tendency of inflammation to confine itself to that tissue in which it springs up, along which it is propagated especially by continuous sympathy; though exceptions often occur (§ 133, 141, &c., 498, 500). What is true of inflammation in this respect is probably, also, of other morbid states. The reason is to be found in the natural modifications of the vital properties of the different tissues. This modification existing in different parts of one and the same continuous tissue commonly limits the continuity of inflammation to a particular part of the tissue, though it often spring up in other parts of the tissue by reflected nervous actions (§ 134, &c., 500, 674 d).

The foregoing general limitation of any given form of disease to the tissue first invaded (excepting as other tissues of the same compound organ are more or less disturbed in function) is especially remarkable of the *common* form of inflammation, and of diseases that are not distinguished by obstinate conditions, such as specific inflammations with strongly-marked characteristics; as scrofulous, venereal,

carcinomatous, &c. (§ 149-151, 525-531).

REMOTE CAUSES OF INFLAMMATION.

742. The remote causes of inflammation fall under the general considerations already made (§ 644-666). As all the agents which contribute to its production must be included in the category, such as are naturally salubrious, or necessary to the purposes of life, as food, &c., sometimes fall within the comprehensive class. It is mostly, however, the abuse of such agents which renders them predisposing causes; but they may readily prove exciting when other causes have laid the foundation of predisposition.

743. It only remains to be added upon this subject, that I cannot agree with distinguished vitalists that stimuli are alone the predisposing causes of inflammation and fever; but there can be no doubt that a right decision of the question is of practical importance. Upon it may depend, for example, the proper treatment of cerebral affections arising from excessive doses of opium. In excessive doses, it is generally conceded to be directly sedative; and yet is profound

cerebral congestion one of its morbific effects, for which bloodletting is the most efficient remedy. Hydrocyanic acid will do the same thing, which, in like manner, is best relieved by loss of blood (§ 483, 484, 494 dd, 827 d, 828). And so of extreme cold, the philosophy of which is set forth in the Commentaries (vol. ii., p. 478-493.) Tartarized antimony is powerfully sedative in all its doses, and the larger the more so. Yet in its over-doses it produces a serious form of inflammation. Even excessive bloodletting may lead to inflammation, for which the farther abstraction of blood by means of leeches may

be useful, or at least so it is said (§ 1024 à, 1057).

Concentrated miasmata, when followed immediately by an attack of fever, evidently depress the powers of life, as one of the first changes which they establish (Commentaries, vol. i., p. 471-474). We must take the facts as we find them, and build our theories accordingly. And here we see the importance of looking well to the characteristics of the properties of life, at their wonderful mutability, observe how they may be profoundly altered at the moment when certain morbific causes begin to operate, how they may go down in an instant to a state of extinction; and how, on the other hand, every restoration

from disease is the result of their own constitutional tendency to return,

through a series of changes, suddenly or gradually, to their natural state (§ 175, 177-185, 672, 733 e).

These considerations enable us to understand how the properties of life may be as readily affected by depressing agents or sedatives as by stimulants, and how, when affected by the former, they may speedily react and constitute the absolute conditions of inflammation and fever (§ 666), or return at once to their natural state (§ 150, 151, 227). When either of these morbid conditions actually ensues, there can be no doubt that the organic properties have undergone an exaltation as well as another modification in kind. The physical philosophers will allow nothing but absolute prostration, and a passive relaxation of the vessels, when high arterial action sets in; but they look upon the cold stage of fever as being best explained by something like the "glacier theory." And yet, if we go to the simple facts attendant on the very invasion of fever, we shall find in the universal contraction of the capillary vessels, during the cold stage of fever, abundant proof of the exaltation of mobility and irritability; and this is farther confirmed by the salutary effects of two most depressing agents, bloodletting and emetics. See, too, how local inflammations are becoming generated during this stage; and when the hot stage supervenes, and when, also, in progressive order, the secretions break forth, we have the most unequivocal demonstrations of exalted powers; though here, as in inflammations, this change is only an inconsiderable part of the alteration which the properties of life sustain (§ $188\frac{1}{2}$, $487^{2}h$, 569, 675, 764, 964).

Still, however, in respect to inflammation, its most common causes are directly stimulant, and exalt the vital properties and actions by their direct operation; but this appears not to be equally true of idiopathic fever (Med. and Phys. Comm., vol. ii., p. 213, 241-248, 277-

280, 288, &c.).

Finally, we may not lose sight of the fact that the nervous influence, either reflex or direct, is the immediate remote cause of effects beyond the seat of the direct action of the primary causes (\S 647 $\frac{1}{2}$, 666).

PATHOLOGICAL OR PROXIMATE CAUSE OF INFLAMMATION.

744. "The act of inflammation," says Hunter, "appears to be an increased action of the small vessels. It is commonly supposed to be contraction of the vessels; but I have shown that their elastic power also dilates them, and I have also reason to believe that their muscular power has a similar effect."—HUNTER, on the Blood, &c.

"The blood," says Magendie, "traverses with ease the infinitely more minute tubes that abound in our tissues. There must be some particular conditions to facilitate its passage. What proves their existence is, that if certain alterations are effected in the composition of the blood, it stops, undergoes morbid changes, becomes extravasated and decomposed, and produces the various disorders which pathologists have vainly attempted to explain by the words inflammation. What sense, in truth, is there in applying the word inflammation to our organs? Do our tissues actually take fire?" [So says Vacca, and Magendie is of his school.]—Magendie, in London Medico-Chirurgical Review, January, 1839, p. 208.

"For my part, I declare boldly, that I look upon these ideas about VITALITY and the rest of it, as nothing more than a cloak for ignorance and laziness." "All the physician can do is to order remedies, which, if necessary, the nurse could prescribe equally well." "You saw me give rise, at my pleasure, to pneumonia, scurvy, yellow fever, typhoid fever, &c., not to mention a number of other affections which I called into being before you."—MAGENDIE'S Lectures.—And that, too, upon animals.

"Pythagoras," says an ancient philosopher, "looks at the sun very differently from Anaxagoras. The former carries his eyes into it like a god, while the latter looks up to it as unfeelingly as a stone" (§ 699, 709, 810, 838.—Also, Medical and Physiological Commentaries, vol. i., p. 510-515, text and notes, 518, note, 526, 539, 567, note, 584, 611, 650, notes, 697, 698, as to Magendie. Also, Lehmann, § 1034).

745. No subject has excited more discussion, or more deservedly, than the pathological cause of inflammation, since this affection and idiopathic fever comprise most of the diseases of man, and since, also, the treatment of disease turns mainly upon our conceptions of its path-

ological character (§ 4, 667-677).

The example of inflammation involves the whole philosophy of all other diseases; and, if our views be right in respect to this affection, we shall have little difficulty with any other. This I shall endeavor to show by a special consideration of fever and venous congestion. The general laws are the same in all the cases; though the results are variously modified. There may be, for instance, in one form of disease increased action of the extreme vessels, an exaltation of the vital properties, &c., while in another form an opposite condition may obtain. Yet these opposite states shall depend upon the same great general laws. In either case, for instance, it is a general law that an altered condition of the organic properties constitutes the essential pathology; and, it is another general truth that this altered condition has been instituted by deleterious agents. The changes in function will also correspond with the particular changes of the organic properties. But, coming to the details in respect to the exact nature of the changes, we find them different in the different cases; and they depend mainly upon the specific nature of the remote causes, which have altered the properties of life in one series of cases in a different manner from the other series (§ 652). These, therefore, are only contingent results, and do not affect the great laws which are concerned

about the essential pathology of disease.

746, a. The extreme terminating series of the arterial system of vessels are the immediate instruments of inflammation. They are endowed with muscular fibres, and perform, naturally, the function of active contraction and dilatation (§ 384-387, 397-399). That such are the essential instruments is evident from a variety of facts, of which, however, it is only necessary to state one, namely, the analogy which subsists between the process of nutrition and the reparative process of inferior animals and the formative and adhesive stages of inflammation; while the true suppurative, and all its modifications, are analogous to the general function of secretion (§ 729, 732 a). The effect of cantharides, &c., applied to the skin, is an example in illustration. All this, too, corresponds exactly with what is known of the greater development of the properties of life in the extreme vessels; which, it may be now said, supplies an important proof of their increased action in inflammation (§ 407 b, 410, 411).

Such, too, are some of the numerous instances in which we reason with certainty from analogy, especially in relation to organic life; while the conclusions are corroborated by all the relative facts.

I have thus thought it important to indicate with precision the instruments of inflammatory action, that they may not be confounded with that series of capillary vessels which serve mainly as reservoirs to the extreme vessels, and between which there is also a broad distinction in their vital states. We shall have accomplished much in establishing the vital character of inflammation, and in exposing the errors of the physical hypothesis, by the plain fact whose statement is made as a point of departure and for the government of the whole inquiry. Those vessels, as I have endeavored to prove, are eminently characterized by the attributes of life, and I hold it to be fundamental, and cannot be denied, that what is physiologically true is true, also, of those morbid states which coincide in their general results with the physiological (§ 41–44, 48, 52, 134, 135, 136, 409 c-411, &c., 516 d, no. 6, 524 a, no. 1, 526 a, 1039, 1040, 1056).

If such, therefore, be founded in nature, the essential philosophy of inflammation is to be found in modified states of the natural properties and functions of the extreme series of the arterial system.

746, b. The absorbents, also, are interested in the ulcerative pro-

cess, and are, therefore, modified in their action.

746, c. The nerves, from constituting a part of all the tissues, and from the liability of every part to be affected by preternatural determinations of the nervous power upon them, and being, also, the organs of sensibility, are so far liable to a participation in the pathological states of inflammation, and in affecting the secreted products (\$ 456 a).

From all that has been said, it is evident that the nervous power can act only as a remote cause of morbid changes, and that the conclusion is unavoidable that all the remote causes of inflammation, as of every other disease, produce their morbific effects upon the organic properties, that the morbid processes are carried on by these properties, as in the vegetable kingdom, and that the nervous system is not

necessary to the disease, however it may exert a profound influence both upon the actions and products (§ 227, 233\frac{1}{2}, 475\frac{1}{2}, 507, 647\frac{1}{2}).

The nervous power, it is true, is the immediate remote cause of all inflammations which spring up sympathetically, but it forms no part of the essential pathological cause; nor are the nerves in any other way the medium through which inflammations are excited ($\S 201-204$, 226, 233, 405, 446 a, 500, $647\frac{1}{2}$, 715, 725 c, 902-905, 1039, 1040).

On the other hand, the physical philosophers, with singular inconsistency, maintain that the "nervous influence" has an important agency in the inflammatory process, though they do not say in what that agency consists, or how it co-operates either with mechani-

cal or chemical agencies (§638½).

747. Hunter laid the foundation of the true theory of inflammation. He supposes that the vessels are in a state of increased action, both as to contraction and dilatation, and that, in a general sense, they carry

an increased quantity of blood.

Irritability and mobility, the two great properties upon which or ganic actions mostly depend, are probably always increased and otherwise variously modified in all inflammations. In consequence, also, of the increase of irritability all inflamed parts are more than naturally susceptible of the action of stimuli, though not according to their ordinary effects in health. It is a general law, indeed, in respect to all diseases, that the natural relations of the affected parts to physical and mental agents are more or less altered; and upon this turns, mostly, the curative action of medicine, &c. (§ 143, 149–152). It was a radical defect in Hunter's doctrine that he did not consider the altered condition, in their very nature, of the vital properties, but imputed the essence of inflammation to a simply "increased action of the powers of the part." If the hand be plunged into warm water, there ensues an increased action of the vessels, but there is no inflammation.

748. A theory opposed to the foregoing, and now universally adopted by the physical school of medicine, supposes,

1. That the vessels concerned in the process of inflammation are

passively relaxed.

2. A progressive accumulation, stagnation, and coagulation of blood

within the vessels (\S 789).

3. An enlargement of the collateral vessels proportioned to the redundancy of blood transmitted to the part, occasioned by the force of the vis a tergo.

4. That the blood is propelled through the collateral vessels by the

action of the heart (§ 392).

5. That the vessels, being paralyzed, relaxed, and mechanically obstructed, can perform no part in generating the products, or in those processes already described as the results or "terminations" of inflammation; but, on the contrary, that all the fluids are mechanically strained off from morbid blood, notwithstanding the mechanical obstruction occasioned by the coagulation, and that ulceration is only a mechanical softening of the living solids. (See "Report of the recent State of Knowledge of the Nature of Inflammation," by Mr. Wharton Jones, in British and Foreign Medical Review, April, 1844.)

749. Such is the prevailing mechanical doctrine of inflammation, which, in conformity with the plan of this work, I have here intro-

duced as appearing to me the most adverse to facts and philosophy, but sustained by a powerful school. I shall not enter upon its farther refutation, nor upon the proof of the vital theory, beyond the statement of a few prominent facts. Both of these objects I have endeavored to accomplish in the *Medical and Physiological Commentaries*, nor have I seen any fact whose import is not there considered (vol. ii., p. 141-214, 224-397. Also, my "Introductory Discourse," p. 22, &c.,

1842, in vol. iii.).

The mechanical doctrine of inflammation has grown out of experiments by which Nature is misrepresented. I mean that such is my opinion; but not without its attendant reasons. One experimental fallacy, however, lies mainly at the foundation of all the foregoing conclusions, which consists in the means by which inflammations are artificially produced for the purpose of arriving at a knowledge of their pathology. Irritants of a chemical nature have been applied to delicate membranes, by which their organization is impaired or destroyed, and the blood also coagulated by direct chemical influences. The part has been then subjected to the microscope, under the direct rays of the sun, whose heat has the effect of drying the disorganized tissues, and consolidating the blood. Let rubefacients be a test.

From such most unnatural results the whole organic process of inflammation, its formative stage, the stages of suppuration, ulceration, and the secretion of lymph, of serum, &c., are interpreted upon

purely mechanical principles (§ 396, 410).

But, if this were true of inflammation, it should be equally so of the analogous results in the healthy state of the body; and growth itself, and all the secreted products, should be equally determined by mechanical laws. Were the doctrine, therefore, founded in nature, it would completely overthrow the whole science of physiology, and re-

duce the living being to a mere automaton (§ 639 a, 746 a).

750, a. We have already variously seen what analogy prompts. We have seen, too, that it has been demonstrated that the blood is accelerated in the capillary and larger vessels when stimulants are applied to them, or to the brain or spinal cord, and that they give rise to alternate actions of contraction and dilatation, even in the veins (§ 384, 387, 392, 399, 408-411, 480-485, 498 e). We have seen how the extreme vessels become enlarged and admit the red globules (§ 192). We have seen, physiologically, that all the vessels must have an independent vital action (§ 382, &c., 407, 410, &c.). And now I ask the physical philosopher, upon his own ground, how the extreme vessels in dense structures, such as ligament, cartilage, and bone, acquire their great enlargements in their inflammations? It is evident that the physical philosopher has limited his views, as he has his experiments, to soft, delicate membranes. He has reasoned from an isolated fact, and that fact evidently of a spurious nature (§ 54, b,c).

That there is generally, though not invariably, an increased volume of blood circulating in the instruments of inflammation, is shown by the increased quantity of blood which flows from the veins of an inflamed part; by the high florid color of the part, and of the blood; by the profusion of blood which follows scarifications and leech-bites; by the rapidity with which the blood returns when expelled, by rubbing, from an inflamed surface; by the actually increased fluidity of the blood proceeding directly from the seat of inflammation, as shown

by its slower coagulation than in health; by the preternatural generation of heat, which even no chemical theory can explain without admitting an increased circulation of the blood; by the profuse secretion of certain fluids, and their specific nature; by the frequently increased pulsation of an artery leading to an inflamed part, and especially as the pulsation is often strongest when the general circulation is prostrate, and again, on the other hand, as the throbbing of the vessel often subsides when the force of the general circulation rises under the influence of the lancet; while the local inflammation may

go on increasing, &c. (\ 1056).

750, b. Coincident with the numerous physical and pathological facts which lie at the foundation of the vital doctrine of inflammation are the effects of remedial agents; since bloodletting, cathartics, antimonials, and other depressing agents, should increase the supposed relaxation of the vessels, and stagnation of blood, both by their direct action and by diminishing the force of the vis a tergo; while, on the other hand, tonics and stimulants should be the prevailing means of cure. Nor can the curative effect of the former agents, nor the morbific of the latter, be interpreted on any other than physiological principles. How, again, will the physical philosopher explain the instantaneousness with which moderate bloodletting, nay, even syncope without the loss of blood, will sometimes overcome pneumonia, inflammation of the brain, &c. (§ 951)? How explain the rapidity with which croup will yield to the prostrating effect of antimonials; or how deep-seated inflammations take their departure as soon as the same condition is produced in the skin by cantharides, or yield more gradually to the silent influences of antimony, ipecacuanha, mercurials, iodine, colchicum, guaiacum, veratria, quinia, &c., according to the special modifications of the disease by its various remote causes (§ 150, 650-653, 662 b, 668, 669, 672, 674, 742, 935 d, e)?

751. I have just intimated that, if vital action do not exist, there should be no varieties of inflammation. It should be all small-pox, or lues, or rheumatism, or, at least, all of the common variety. The vital phenomena and physical products should be always the same; the same in all tissues and in all constitutions (§ 409, c-i). Nor should we have any remarkable and diversified sympathetic influences of inflamed parts upon the system at large (§ 500, 512-530). The vitalist supplies the only intelligible solution of the facts which are presented in real life. He points to the various modifications of the organic properties, according to the peculiarities of every tissue, the diversities of the remote causes, constitution, age, sex, &c., which he believes, also, to be the foundation of all rational pathology; and upon the same principles he interprets the curative effects of remedies.

Active and Passive Inflammation.

752. I endeavored, originally, in the Medical and Physiological Commentaries, to show the fallacy of the distinction of inflammation into active and passive, and to prove the dependence of all forms of the disease upon one general pathological cause; and I shall now briefly advert to the manner in which the principles set forth in the present work establish that conclusion.

753. In the active form of inflammation there appears to be a vague recognition, so far as the verbal distinction goes, of the morbidly-in-

creased action of the part, while in the passive form all is "relaxation" and "stagnation" (§ 748). These exactly opposite states of verbal pathology are especially characteristic of the school who maintain that inflammation is always constituted by a passive relaxation of the vessels and coagulation of blood. With the same consistency they also affirm that the two nominal conditions require opposite modes of treatment; though, in justice to the real hypothesis, it should be said that the stimulant plan is apt to prevail. There are many authors who speak of an active and passive state of inflammation as things in absolute opposition, but they attempt no explanation of the supposed distinction.

Andral perceived that the term *active* is not in harmony with the mechanical philosophy of the disease, nor with his own views as to the abolition of the general term; and he therefore substitutes *sthenic* and *asthenic* to express the opposite conditions, and *hyperæmia* in the place of inflammation. But the epithets are as much in direct opposition

as active and passive (§ 699, c).

754. But it requires only a right exercise of judgment to understand that the same disease cannot be constituted by opposite pathological conditions (§ 741, b). The supposition contradicts itself. The varieties depend simply upon partial modifications of a common pathological cause; and this conclusion, as abundantly exemplified, is of no little practical importance (§ 766). The term passive can only be intended, by those who use it, to inculcate a stimlant treatment, and that mechanical condition of the blood-vessels whose refutation I have attempted extensively in the Commentaries.

755. Again, in the supposed opposite conditions, the vital signs, and the morbid products, are nearly identical; which evinces, sufficiently, a close affinity in the pathological states, while the analogy between those products and such as depend on the natural processes places both modifications of the disease on a common physiological founda-

tion (§ 137 e, 150–153, 639, 746 a, $694\frac{3}{4}$).

756, a. The occasional success of tonics and stimulants in the treatment of inflammation, whether applied internally or externally, or with or without antiphlogistic remedies, is no evidence, as supposed, of a pathological state manifestly different from that which is most readily surmounted by loss of blood, cathartics, &c., alone. This will be obvious when the true modus operandi of remedial agents is duly considered (§ 150–152, 638, 893, &c.). It is also well known that a sudden and powerful impression even from alcoholic stimulants will sometimes subvert an inflammation or a fever of great activity, which, under apparently the same circumstances, would be aggravated by such treatment in the hundred next following cases, but where loss of blood, &c., would be speedily curative in nearly all (§ 900, 904 d). The disciples of Brown have been thus enabled to sustain themselves in the midst of general failure.—Note Ee p. 1133.

Take a clear example, which illustrates the only distinction, so far as principle is concerned, between the supposed opposite conditions of inflammation. Such a one occurs in this disease when modified by the predisposing cause of intermittent fever. Here the Peruvian bark may be as necessary to its cure as the loss of blood, though the latter is commonly, also, more important. And there occurs to me a proof from analogy which demonstrates the vital doctrine of inflammation;

which consists in the fact that the Peruvian bark is also a specific for intermittent fever, while, as with inflammations, it will aggravate other forms of fever. If, therefore, it be admitted that there is no "stagnation of blood" in the intermittent and other fevers, it clearly follows

from this analogy that there is none in inflammations.

The intense inflammations attendant on scurvy often yield only to such remedies alone as improve the digestive organs, of which tonics may be one; and here we witness impressive demonstrations of the laws of sympathy (§ 500, 512, &c.). And yet in the same conditions bloodletting may be simultaneously appropriate or necessary. Opposite modes of local treatment succeed in burns and scalds; catarrh is often cured by "gin sling;" erysipelas has apparently yielded to the tonic and stimulant practice, though at the hazard of life; and typhus fever, with its train of local inflammations and congestions, divides the medical world into the two opposite systems of treatment.

Again, the most feeble subjects are quite as likely to require the depletive treatment, in grave inflammations, as the robust; and long-continued chronic inflammations have often yielded to a repeated loss of blood where tonics had been employed under the illusive doctrine of passive inflammation (§ 1007 b-d, 1008, 1019).—Note II p. 1139.

The differences in small-pox, varioloid, and cow-pox, which are essentially one disease, illustrate the principles before us. So, too, do all the varieties attendant on specific forms of inflammation, as measles, scarlatina, lues, rheumatism, &c. Lues yields especially to mercury; rheumatism to colchicum and guaiacum; scrofula to iodine, &c.; and yet the simultaneous loss of blood may be more or less useful or indispensable. The example of tuberculous phthisis is illustrative of our whole subject. A mixed, or even a stimulant, treatment is slow in its destructive effects; and its evils have been, therefore, overlooked in the speculative views which morbid anatomy has suggested as to the nature of the pathological change in which tubercle originates (§ 695, &c.), and in the brown chicken-meat which chemistry has contradistinguished from the white. This morbid condition has been recently and extensively considered non-inflammatory, and as supposed by Louis when the most extensive inflammatory lesions and products have supervened; and it supplies us with another exemplification of the irresistible tendency of theory, true or false, to determine the treatment of disease (§ 4). The antiphlogistic practice has been abandoned. But what are its results? Has the mortality from phthisis diminished? On the contrary, it has most fearfully increased (Medical and Physiological Commentaries, vol. ii., p. 622-633, 743-752).—Notes F p. 1114, Мм р. 1141.

756, b. However varied may be some of the remedies in the different modifications of inflammation, the general principles of treatment are substantially the same. The incidentally favorable effect of local or constitutional stimulants is no proof that the pathological conditions of inflammation are not closely allied. It only proves their effect in altering the vital properties in such a way as will enable Nature to take on the restorative process. Least of all can opposite principles prevail at different times and in different climates. It has been so from the earliest records of disease. Otherwise, medicine would consist only of an unconnected series of observations. There would be no principles, and of course no science. Medical learning would

be useless, and experience would suit only the present occasion. A new system of treatment would have to be devised for every climate, every constitution, and every reappearance of the same disease.

But Nature is not thus the creature of accident. It is not Nature who is inconsistent, or who operates by conflicting laws. Art may give her this appearance; but still I say, that "Nature can never deceive." It is owing to this consistency of Nature that medicine had long since become a noble science; difficult and concerned about all other sciences, and therefore taking the lead of all others. A science of principles deduced from the phenomena of Nature, and which, with the facts that are known, conduct us with remarkable certainty to facts that are unknown. It is here that well-founded principles enable us to see farther than the senses, and to learn from a single vital phenomenon, from the expression of the eye, the existence and nature of those latent changes which too many can see only when seeing is useless, and bring upon art and philosophy the derision of the crowd (§ 704, 1005½, 1006 f-1007 d, 1068 a-d).

A sound principle in medicine is like the calculus in mathematics; and what are falsely called "exceptions to general principles" are nothing more than variations in phenomena, which arise from the instability of the properties of life, and the vast variety of influences to which they are exposed (§ 177-179, 237). These variations may denote only partial modifications of a common morbid action, arising especially from differences in the remote causes (§ 644, &c.); or, they may depend upon the same action affecting different tissues; or upon the morbid condition of particular organs affecting certain other organs, or all others (§ 117, 129, 134, 137, 529, &c.); or, upon age, sex, constitutional peculiarities, and other accidents (§ 335, &c., 570, &c.). And, although there be one leading principle in the treatment of such cases, there are other subordinate ones founded upon the modifications. These are to be nicely balanced, that the governing principle may be properly directed (§ 675). But, it is only men of correct thinking and close observation that can apply these principles. All others will look upon the variations of symptoms from their usual state in any one disease, or upon the differences in the results of an exact methodical practice, as denoting very different pathological conditions, or as constituting "exceptions to general principles;" and "bark and wine" will therefore obtain in numerous cases where bloodletting is the only efficient remedy.

FEVER.

757, a. Important distinctions between the two great classes of disease, Inflammation and Fever, have been already sufficiently indicated. The former, as we have seen, is limited to certain parts, while the latter invades the body universally from its beginning. I have reserved for this place, however, a fundamental distinction, which, as a characteristic of inflammation, has been described. This consists of the morbid products, new formations, and lesions of structure, to which inflammation gives rise. It is otherwise with fever, whose distinguishing phenomena are mostly of a vital nature, and whose morbid physical products consist only of modifications of the natural secreted fluids (§ 764, e). Morbid anatomy, therefore, reflects no light whatever upon the pathology of fever. And yet is its treatment, all

its varieties, as well ascertained as that of inflammation and its varieties. Indeed, of most of the varieties of inflammation morbid anatomy does not afford the least information; and yet is the specific treatment of the most common and important, such as rheumatism, gout, intermittent, scrofulous, &c., as well known as the general remedies for inflammation. And so with the varieties of fever. I say again, therefore, that the morbid anatomist may not appropriate what so eminently belongs to the acumen of genius in its philosophical observa-

tion of the phenomena of nature (§ 695, &c.).

It is plain, therefore, that all those who would render morbid anatomy the principal basis of pathology can have no definite views of disease. The effects are mistaken for the cause; and if the former be not present, the case is regarded as inscrutable in respect to its pathology. Every disease is, of course, to the morbid anatomist circumscribed to the organs which tell upon his senses; the varieties in inflammation are overlooked from their want of tangible distinctions; and as ulceration, and some other lesions of inflammation, may happen to appear red or white, they are denominated, as by Louis, inflammatory or contra-inflammatory.

757, b. Many of the ordinary and most characteristic symptoms of inflammation are wanting in fever; such as hardness and incompressibility of pulse, buffing and cupping of the blood, local pain, &c. This is very obvious in intermittent fever. Exalted heat probably takes place in all inflamed parts; but a sunken temperature is common in fever (§ 712-722). Reflex nervous actions supply a test (§ 720, 893).

758. Fever, like inflammation, has numerous modifications, as a necessary result of the constitution of the vital properties, the variety of morbific causes, the unequal distribution of the disease, &c. These modifications have given rise to the distinctions of continued, intermittent, remittent, typhus, nervous, bilious, yellow fever, plague, &c. But strong analogies prevail among the whole; the general pathological cause, as in inflammations, being essentially the same. Most of the varieties in fever depend, indeed, more or less, upon the modifying influences of coexisting inflammations and venous congestions, though more so upon the predisposing causes, while, also, the modifications which grow out of these local affections will depend much upon their particular seat. Some organs, also, sustain a greater burden of the febrile disease than others; and this, of course, will give to every case certain peculiar modifications (§ 134, &c., 644, &c.).

759. Fever, in its most simple form, is of short duration, never continues three days, rarely longer than twenty-four hours, and sometimes terminates within four hours. This is the *ephemera*, which may be taken as the type of the complex forms that consist of a series or

repetition of paroxysms.

The foregoing may be also noticed as a broad fundamental distinction between fever and inflammation; since the ephemera, a perfect representation of fever, may sweep through its course, and terminate as suddenly as it invades the body, and in less than twelve hours, and

leave scarce a vestige of its former presence behind.

760. If fever, therefore, be continued beyond a single paroxysm it is made up of a succession of paroxysms. Many have supposed that every compound case consists of as many fevers following each other as there are paroxysms. This, however, is not pathologically true;

since the same morbid predisposition in which the first paroxysm originated remains, and is the cause of each succeeding paroxysm, and, therefore, a connecting link among the whole. The supposed distinction consists only of periodical abatements of one continuous disease (§ 514 g, 516 d, no. 6, 665, 666).

761, a. The foregoing abatements of fever are the results of salutary efforts of nature, and are variously pronounced as to their degree and duration (§ 733). They are most perfect in intermittent fever, in which they vary from a few hours' duration to one or more days (§

675).

761, b. These abatements of fever, often amounting to an apparent termination of the disease, supply a fine illustration of the recuperative nature of the properties of life, and of their inherent tendency to maintain themselves in a state of integrity. We see, too, the modus operandi of art in its use of physiological laws, when, by the interposition of remedies the natural abatement of fever is confirmed by new influences that are different from the original morbific ones (§ 675, 897, 898, 901, 237, 239, 447 b, 639, 839, 854, 856, 900, 905).

762, a. Each paroxysm of fever consists, in a general sense, of a certain succession of symptoms, which, however, are liable to great variations; and new ones that may spring up in the progress of disease, from accidental influences, may present a general aspect more widely different from the preceding than the near identity of the pathological cause would lead us to suppose. These differences spring from the very susceptible nature of the properties of life, especially in their morbid state, and the various new influences which may operate upon them; and the manifestations are liable to exceed the ratio of any change that may be wrought in the vital conditions. A slight change only, some error in diet, by instituting morbific reflex nervous actions, may give rise to new and striking phenomena, or they may be forcibly presented by the transient effect alone of some momentary cause, as an emotion of the mind (§ 740, 1067).

762, b. In presenting a summary analysis of fever, I shall first consider the *Ephemera*. Secondly, fever as constituted by a repetition of the same paroxysm, and in different modes. Thirdly, the remote causes of fever, the coexisting inflammations, &c. Fourthly, the path-

ological cause.

763. The ephemera, as I have said, may be taken as the general type of the entire family of fevers. It generally commences between six or seven o'clock in the morning, or five or six in the evening; a coincidence of difficult explanation, but manifestly connected with some natural periodical mutations in the vital states of the system (§ 768). It has three distinct stages, which are commonly present; namely, the cold stage or cold fit, the hot stage, and the crisis.

764, a. The first, or cold stage, is the period of the most intense morbid action. Its invasion is marked by a sudden contraction of all the capillary blood-vessels, and consequent determination of blood about the right cavities of the heart, by a diminution of the fluid products, by reduction of temperature, and by a loss, in various degrees, of the voluntary control over the muscles. These are the most obvious changes; and such as relate to organic life evince a universality of the disease at its invasion. Here we may stop to observe another broad distinction between fever and inflammation; since the latter

does not begin in the foregoing manner, but with an enlargement of

the capillary blood-vessels (§ 712, &c., 757, 759, 770).

In idiopathic fever, many of the prominent, but less important, vital symptoms, so far, at least, as sensation is concerned, appertain to the organs of animal life. Those of the organic system are less remarkable at first, as natural sensibility is here inferior to its condition in animal life. The eye, for instance, is naturally more sensible than the intestines, and hence an affection of the former is more conspicuous than of the latter, till disease, at least, may develop the property in the intestine. The same rule, in a general sense, will hold as to the individual organs in either division of life, at this early stage of fever, and is applicable to all other diseases. There may be more disease in one organ than in another, yet the symptoms of that which is most affected may be less strongly pronounced on account of its natural inferiority in sensibility, and often, also, of irritability (§ 133–139, 188, 194).

A preliminary condition, subsequent to the formation of the predisposition, and immediately antecedent to the cold stage, may be recognized under the denomination of access; a term which has been employed to denote the cold stage, or the most intense degree of morbid action, and which, being already formed, cannot be regarded as the access of disease. Prior to the absolute seizure, however, there is commonly a more or less obvious failure of the living powers to perform any of their functions in their perfect manner; and that constitutes the true access of the complaint. The distinction and the term are practically useful as leading to sound pathological views, and to correct treatment.

The development, or attack of fever, is always sudden, whatever the duration of the predisposition; and this is one of distinguishing marks between fever and inflammation.

764, b. After the cold stage has continued for an indefinite time, the diseased conditions begin to assume a tendency toward their natural state, or to obey the great restorative law, the vis medicatrix natura. This recuperative effort introduces the hot stage, which is the first part of the natural cure. The prominent characteristics of this stage are an expansion of the capillaries, an increased volume of blood at the circumference, greater force of the general circulation, and an exaltation of temperature above its natural standard.

A spontaneous change has happened in the vital conditions of the whole body. The small vessels expand in consequence. Irritability has become more susceptible, but less profoundly altered, and the blood accumulated about the heart in the cold stage now rouses that organ to greater action, while it receives concurrent reflex nervous influences from the changes which are going forward in all parts of the capillary system. An increased volume of blood is thus sent out, and this is harmoniously met by the active expansion which is taking place in all the small vessels (§ 384–387). But this is only a part of the involutions of reflex nervous actions which are now in progress.

Notwithstanding, however, the hot stage is the beginning of the natural cure, the symptoms would often denote an increase of the morbid condition, and frequently call for the intervention of art. Nature may be excessive in her aims at reparation. She may overstep her ordinary limit, and push the organs of circulation with a ve-

hemence that shall light up inflammations, and call for an outlet of blood as an indispensable means of prevention (§ 674, d). But we know, from the general progress of symptoms, and the final result, that a succession of favorable changes has been instituted from the

beginning of the hot stage.

764, c. The crisis follows next. This constitutes the greatest decline of the disease. The phenomena of health are now more or less pronounced. The secretions break forth, morbid at first, but rapidly assuming their natural character. Among these perspiration is the most obvious; and hence this stage of the disease is universally known as the sweating. The designation is too partial and hypothetical, since the volume of bile, or of urine, may be quite as redundant, or more so. Crisis is more comprehensive, and implies exactly the things which are in progress. The hot stage is better named; for exalted temperature is the beginning of the elaboration of redundant products, and, for a while, it stands alone. And here I may refer to this connected series of physical products, during the curative stage, as showing analogically the dependence of sweat, bile, urine, and the elevated temperature, upon common physiological principles, and in which alterative reflex nervous actions take an important part (§ 224, 226, 446-447, 461; 475-491, 503, 512, 902 g).

764, d. The secreted products, although the result of improving pathological changes, contribute, as in inflammations, to the ultimate design of nature as depletory remedies (§ 732, 733 e, 757 a).

764, e. In consequence of the foregoing remarks it may occur to some that there is a greater affinity between fever and inflammation than I have admitted (§ 712, &c.). But that conclusion does not follow from the course of nature in her restorative movements. The cold stage of fever may be the period of the most profound disease, and nature may be emerging toward her healthy standard during the stage of reaction, and yet the apparently analogous excitement of the general organs of circulation, and of the immediate instruments of the morbid process in inflammation, may be the stage of most profound disease; and this is known by the various attendant facts.* The pathological conditions, indeed, are so widely different, that the general arterial excitement attendant on inflammation is not, as in fever, followed by augmented perspiration, bile, &c. The increased products are relative to some particular part, and are not of the nature of those which attend the restorative process of fever. one disease they proceed from a tissue, in the other from compound organs. One affection besets the tissues in their individual sense, the other in their compounded sense. These are, therefore, other broad fundamental distinctions between fever and inflammation (§ 141 b. 148, 675, 712-722, 757, 759, 764 a, 770).

765. If a repetition of the paroxysm take place, the crisis is always imperfect. Their repeated occurrence is said to form a compound fever; but, as we have seen, the disease is as much an entire

whole as the ephemera (§ 759, 760).

When the paroxysms apparently go off entirely the fever is called an intermittent. When the interval is less perfect, or a new paroxysm takes place in the middle of a crisis, the disease is called a remittent. When the disease continues without much abatement of symptoms, or, rather, if a new paroxysm set in during the hot stage of a prece-

* Inflammation, as a general fact, is not introduced by a chill, but chills often precede suppuration, when disease is subsiding.

ding paroxysm, it receives the name of continued fever. Between the remittent and continued fevers, however, there is no well-defined line of distinction, as it respects the succession of paroxysms. Again, the remittent and intermittent interchange with each other; and it is even common for one attacked with a remittent to have the intermittent form before his recovery. When, also, intermittents are badly treated, they are often converted into a remittent; which is commonly a

more intractable form (§ 557).

766. We have thus a series of analogies which connect the continued fever with the intermittent; and when we regard the distinct nature of the paroxysms of an intermittent, we see that the ephemera is a representation of each one. The symptoms also confirm these conclusions; from which we learn, more and more, that the essential elements are the same in all the preceding forms, and other minor varieties of the disease (§ 557, 650, 652, 670, 741 b, 754, 756 b). The existence of this coincidence corresponds with the like attribute of inflammations; the varieties of which, respectively, are not more remarkable in their vital manifestations and results than are the natural modifications of the vital properties in different tissues (§ 133–137).

767, a. Notwithstanding, however, the foregoing analogies (§ 765, 766), the causes of continued fever are so far different from those of the remittent and intermittent, that the first of these varieties does not interchange with the last, as do the last two with each other, although the quotidian and tertian types are sometimes manifested with considerable distinctness during the progress of continued fever. Remittents and intermittents are, also, rare in climates where the continued fever occurs, while the former go together, and have close affinities

in their predisposing causes (§ 652, &c.).

767, b. We see, therefore, more and more, the fallacy of the doc trine which regards disease as a unit, and especially as propounded by one to whom medicine is under the deepest obligations. There are, indeed, no two cases precisely alike in their pathological conditions; and there is scarcely a principle of greater importance (§ 673, 857). It is true of diseases which are most allied, and even true of the same case during its advances or its decline; and coming to the specific forms of inflammation, and passing from those to idiopathic fever and the various modifications of this disease, and regarding in connection, also, the more obscure pathology of the various conditions of the stomach which are grouped under the general denomination of indigestion, and all those states which go to make up the "nervous disorders," we can scarcely fail of escaping from the illusions which have grown out of the physical views of disease, or of turning ourselves to that philosophy which concerns the mutability of the properties of life (§ 177-184, &c., 780).

768, a. In a vast proportion of all the cases of fever the paroxysms take place in the afternoon; generally beginning about five or six o'clock, and going off about five o'clock in the morning. This is common to all constitutions; nor is it much regulated by the force of morbid habit, but rather by its association with a natural evening paroxysm, to which all individuals in health are liable, and which happens and subsides about the foregoing hours, even when traveling to the eastward or westward (§ 772, b). This natural paroxysm is marked clearly by its phenomena; and the foregoing coincidence shows.

again, how the physiological laws hold their control in disease (§ 133-152, 638). A coincidence is farther seen in a diminution of the secretions attendant on the natural and morbid paroxysm. A purgative given now, whether in health or disease, irritates the system more than at any other time, and produces smaller evacuations than in the morning, especially if rapid in its operation. On the contrary, in either case, if the cathartic do not operate till morning, the discharge will be far more abundant. Toward morning the natural paroxysm subsides, sweating often comes on, and all the functions of the body and mind are then manifestly improved. And so, more or less, with the morbid paroxysm. The former is not connected with the fatigue of the day, since it is common to mankind under every condition of

repose, employment, and habits.

Again, the first paroxysm of a fever may take place at any period of the day; the time of the invasion often depending upon some immediate exciting cause. But, the succeeding ones generally coincide with the natural evening paroxysm; especially in continued and remittent forms of fever. I speak, however, of the disease as manifested by unembarrassed Nature, or when she may be duly assisted by art. Misapplied remedies, and various other exciting causes, will be apt to affect the periodical law, especially where Nature is least recuperative, as in continued and remittent fevers. The regularity of the paroxysm is also influenced by local congestions and inflammations, and this, particularly, when exciting causes are in operation (§ 773). These considerations, independent of their practical bearing, refer to important problems in the philosophy of life and of disease.

The paroxysms of fever, therefore, observe a diurnal period; rare-

ly taking place in the night.

768, b. The foregoing natural paroxysm extends its influences to all diseases, and influences, also, the operation of remedial agents.

769. If a paroxysm return two or three times, or two or three relapses take place at short intervals (as a few days, or perhaps weeks), the force of morbid habit is manifested; since in one case the paroxysms continue to return with greater obstinacy, and in the other relapses are more likely to follow, and this, often, for a great length of time (§ 535, &c., 768 a). Much, however, may be frequently due to supervening local congestions, which keep up the predisposition to fever, and operate, also, as exciting causes (§ 645, 665, 666, 870). Where the intervals are long, the return of the fever is not a relapse, but a new attack; though this is truer of continued than of intermittent or remittent fever. And this leads me to say, that any remote cause of fever is less apt to produce a relapse than to excite the disease in one who has not been before affected (§ 544, 550, 560, &c.).

770. It would be difficult to say why the paroxysms of fever are separated by definite intervals, and these intervals, too, remarkable for their variety as well as precision in the same form of fever. They show us at least, however, the absurdity of expounding disease by any of the laws or agencies that are known in the inorganic world. These definite intervals have given rise to several designations of the same form of fever; and according to the interval so is the type. We

have nothing like this in inflammations (§ 712-722, 764 e).

771. In the continued form of fever, and in remittents, the paroxysms (or exacerbations, as they are then called) recur about once in

twenty-four hours; but the interval is more indefinite than with intermittents. In a majority of the cases of intermittent fever the paroxysms are repeated at the end of forty-eight hours, and hence the name of tertian, or tertian type. The next most common are quotidians, or fever with daily paroxysms; each one taking place at the end of twenty-four hours. A third, and most fixed variety, is called the quartan, having a return of its paroxysms in seventy-two hours.

772, a. Sometimes there is a periodical difference in all the varieties, or types, of the intermittent, of four hours; and if, as now and then happens, the difference be greater, the fever is said to be *irregular*. These irregularities are commonly owing to local congestions, or other accidental influences, the removal of which will generally es-

tablish the more definite interval.

772, b. When the foregoing deviations occur, the paroxysms may either anticipate the usual hour, or be delayed beyond it; and it is a remarkable fact, and strikingly illustrates the law of vital habit (since it is inobedient to the influence of the natural paroxysm of health), that in such cases the paroxysms are apt to go on with the particular

irregularity with which they began (§ 544, &c., 768 a).

772, c. Another remarkable fact connected with the intrinsic nature of the vital properties, and illustrative of the special institutions of organic life, relates also to the inequality of the foregoing intervals. That is to say, if the interval of tertian paroxysms, for example, deviate from forty-eight to forty-six hours, or, on the other hand, from forty-eight to fifty hours, the occurrence of the paroxysms will be growing earlier in the former case, and later in the latter. But this is not the most striking phenomenon attending these cases; for when the paroxysms, by their regular anticipation of the period of each last preceding paroxysm, approach the night, one paroxysm is often lost. This phenomenon, however, has its more obvious foundation, as the others have more obscurely, in the natural law of the body already mentioned (§ 768, a), since there is no inherent tendency in the system to induce a paroxysm during the night (§ 137 b, 149–152, 638).

773. The intermittent and remittent fever are often so nearly allied in pathology, that it is sometimes difficult to decide upon the type. Here the deviation from the regular form of the intermittent is clearly owing to the presence of venous congestions, or to inflammation; since the intermissions will become well defined as soon as those com-

plications are removed (§ 758, 762, 768 a).

774. The natural duration of continued fever is about three weeks, rarely six. It varies with intermittents according to the particular type. Such is the power of vital habit (§ 544, &c.), that a tertian naturally occupies from three to four months; and this is one of the numerous instances in which the advantages of medicine are illustrated, and the philosophy of solidism established; since, as it respects the pathology, an emetic, or a dose of quinine (of no analogous virtues), may so alter the morbid properties as to place them at once in a condition to recover their natural state (§ 557 α , 904 d).

Much, however, of the prolongation of fever is often due to the local forms of disease which supervene on its progress, to errors in diet,

fatigue, &c.

775. Opposed, also, to the humoral pathology, and all the physical hypotheses, is the occasional sudden termination of continued and in-

termittent fevers, in a state of health. This is generally preceded by a severe paroxysm, and the disease is ended at once (§ 557, a). The very violence of morbid action is attended by an alteration of the organic properties which enables them to take on the recuperative process; just as we sometimes see alcoholic stimulants overthrow acute inflammation, or the same conditions of fever (§ 756). Will the chemist or humoralist explain? Fothergill, Falconer, and others, supposed that the full and tense pulse which often supervenes on apoplexy depends upon a struggle which arises from an action of the vives vitæ to restore health. "I believe," says Fothergill, "it happens in most cases where there has been a temporary, or even momentary cessation of the animal powers."

Remote Causes of Fever.

776. I come next to the remote causes of fever, and to consider, also, yet farther, how the general pathological condition, as in inflammation, is liable to modifications by differences in the nature of the remote causes, and how, also, fever is influenced by coexisting inflammations and venous congestions; with a view to farther illustration

of principles of various import.

777. The predisposing causes of idiopathic fever probably consist, in all cases, of the results of vegetable decay (§ 652, 653). The special type and modification of the fever are determined very greatly by the nature of the new combinations; though other influences may contribute (§ 650, 651, 758, 762, 773). The essential causes make their impression so profoundly, that the incubation goes on although the causes may have long ceased to operate; which is commonly different with inflammations (§ 711, &c.). The causes of fever are also distinguished by the peculiarity of so modifying the organic properties of certain parts by their direct action, that the entire system is sympathetically brought into a corresponding morbid state (§ 148, 657 b).

778. The predisposing causes of fever have been considered in all their other relations to the disease under that general division of pathology; their modus operandi, the nature of predisposition, the in-

tervening periods, &c. (\$ 148, 644, &c.).

779. The predisposing causes of fever are also causes of inflammation and venous congestion; and hence it is, in part, that fever rarely continues long without the appearance of one, or the other, or both conjointly, of these local affections. Or, the local may precede the constitutional disease, and become its exciting cause; or the former may exist without developing an attack of the latter, although the system be predisposed to the constitutional affection. Or, again, the explosion of the general malady is very apt to occasion a full development of the local conditions of disease in organs so predisposed. But, independently of this predisposition to local disease, it is the great tendency of febrile action to lay its foundation. The occurrence of these local affections modifies very variously the constitutional disease, and increases its force and obstinacy. The treatment, therefore, must turn greatly upon the local complications, and remain strictly antiphlogistic till they are removed or greatly subdued.

780. It may seem remarkable that diseases which are so considerably diverse in their pathological conditions as fever and inflammation should be produced by the same predisposing causes. But this only

shows that there are analogies among all diseases. All depend upon certain states of the properties of life; and as these properties can never be greatly diverted from their natural conditions till life is at its ebb, there must be affinities among all morbid states. By considering, also, that the vital properties have various natural modifications in different parts we come to understand how the predisposing causes of fever may simultaneously predispose particular organs to inflammation, or venous congestions (§ 133–152, 741 b, 767 a, 786, &c.). What I have said, also, in former sections (§ 662, 670, 675) as to the fluctuating state of the vital properties and functions during the progress of a febrile paroxysm may reflect light upon this subject of analogies.

Pathological Cause of Fever.

781. Coming to the pathology of fever, morbid anatomy yields no assistance, and proves that our conclusions as to the essential nature of disease must be mainly derived from its phenomena during life (§ 695, &c.). It is therefore not remarkable that they who look for the philosophy of disease to its direct manifestations should alone distinguish idiopathic fever from inflammation (§ 695, &c., 712–732, 757, 759, 764, 770).

782. Next to the proximate cause of inflammation no question in medicine has occasioned more speculation than that of fever. The humoral pathology has been at the foundation of many hypotheses, and others have risen upon some supposed change in the organization of the solids. These were the ancient and are now the prevail-

ing doctrines.

783. In no form of fever do the symptoms denote an absolute unvarying affection of any organ; but, on the contrary, the greatest variety occurs as to the force of the disease in different parts. These contingencies have suggested the minor designations as stated in sec-

tion 758 (§ 134, 138, 142, 143, &c.).

784, a. Fever being a disease of the whole body, and constantly liable to complications with local inflammations and venous congestions, it is particularly important that all the attendant symptoms should become elements in forming our conclusions as to the nature and force of the disease, both in a general and local sense, and that our prescriptions should be determined by the aggregate weight of the phenomena (§ 675). Vicissitudes may be also hourly occurring in different parts, embarrassing to the judgment of the practitioner, and demanding its highest exercise (§ 675, 685, 686, 857).

784, b. Owing to the universality of the disease, and the general coincidence in its pathological character, remedial agents, when applied before morbid habit has taken possession, or local inflammations have supervened, will stretch their influence over the universal body, and may institute every where those pathological changes which are capable of a progressive march to their ultimate termination in health

(§ 148-152, 487, 535, &c., 557, 672, 854, 893, &c.).

785. It is the triumph of morbid anatomy that it lays open to the senses the tangible products of inflammation; while it seizes upon what an observation of Nature had already determined as to the pathology of the disease. The great family of fevers shall sustain this position of the vitalist, since here nothing is seen, in numerous cases, after life has become extinct. The knife of the anatomist goes down

to the smallest fibre, and the aid of the eye-glass is summoned in vain. And yet do we know about as much of the pathology of fever, for practical purposes, as of inflammation, and the treatment of one is as well determined as of the other (§ 705). This has been inferred from the vital phenomena of both diseases, and from an observation of the effects of remedies. These phenomena are not less multifarious in fever than in inflammation; and so far as sensible changes attend the immediate instruments of disease there is more to be seen in febrile than in inflammatory diseases. In both there is commonly an increased volume of blood circulating in the capillaries; but there is also, as a common element of fever, a primary contraction of those vessels. What I have now said is the test between organic philoso-

phy and morbid anatomy (§ 1056).

And how is it with the signs which denote the essential pathology? We have seen that the facts are equally clear in both diseases, that there is an exaltation of irritability and mobility from the time of their invasion (§ 743, 744, &c.). But that is all we can learn of the particular changes which they undergo in either affection, and that is only a minor part of the disease. The organic properties and functions have also sustained a change in kind, which is likewise known by the phenomena. It is that change which constitutes, essentially, the diseases, respectively, and which distinguishes one from the other (§ 177-181). The phenomena, however, do not indicate the nature of this essential change; but what they disclose as to the exaltation of irritability and mobility, in connection with their more indefinite suggestions, and with experimental observation, enables us to institute all the pathological and therapeutical principles that are necessary or useful in practice. The rest is concealed, because it would be useless for man to know it.*

The cold stage, or invasion of fever, when morbid action is most profound, is marked, it is true, by an apparent debility of the living powers; so much so, indeed, that it may be difficult to show that this universal opinion is erroneous. In a former section, however, I have attempted it (§ 743). Its practical importance cannot be too highly appreciated, since it deters the practitioner from the use of the lancet, or leads him to that of stimulants; especially in congestive fevers (§ 961, &c.). The error has proceeded, in part, from the very fact which evinces an exalted state of irritability and mobility,-the tonic contraction of the capillary vessels during the cold stage. The embarrassed action of the heart, diminished circulation, sympathetic influences of venous congestions, the partial loss of control over the voluntary muscles, or indisposition of the will to act, and the want of a proper estimate of the properties of life, and of the morbid changes to which they are liable, have contributed their share to this mistaken view of the pathology of fever. Nothing, however, has done so much toward the doctrine of "debility," and the stimulant treatment, as the impaired energy of the will over the voluntary muscles, which arises from the venous congestions that are associated with fever (§ 569, 487, I shall therefore proceed next to the subject of Congestion.

^{*} I had a patient whose head of dense black hair changed in the course of one night to a bright bluish turkey-green, as the result of remittent fever. He recovered, and his hair returned gradually to its former black. I had been before skeptical as to the reputed effect of the nervous influence when excited by fear in changing the hair suddenly from dark to white.

VENOUS CONGESTION.

786. The pathology of venous congestion, its treatment, &c., form an extensive Essay in the Medical and Physiological Commentaries.

For all that relates to the pathology of that disease, as well as of varix, and for an exposure of the errors of former doctrines, and, indeed, for most that is essentially important in that Essay, I claim the merit of an exclusive originality (RIGHTS OF AUTHORS, p. 919, no. 28.)

787. The conclusions at which I have arrived, if founded in nature, are among the most important in practical and theoretical medicine; since the conditions which obtain in venous congestion often demand an energetic practice, reveal the true cause of the extensive mortality which has resulted from the stimulant treatment of fevers, and enforce the admission of some of the most important doctrines in physiology (§ 710, b). The relation, for example, of the pathology of venous congestion to the philosophy of the circulation of the blood, &c., illustrates the vital character, and establishes the elements of that complex function (§ 384-391).

788. During the last century, the enlarged state of the veins, which forms the prominent characteristic of venous congestion, attracted the attention of several writers, who ascribed a malign influence to the enlargement, though they regarded it merely as a mechanical phenomenon. From that time, till a recent period, this state of the veins was lost sight of entirely, notwithstanding it contributes, more than the recognized forms of inflammation, to the mortality of the human race. The neglect of this disease in our own times probably arises from the prevailing disposition to interpret organic phenomena, whether healthy or morbid, upon chemical and mechanical principles.

789. The foregoing enlargement of the veins is an essential condition of the disease, though of minor importance. This enlargement has been universally referred to an obstruction of the current of venous blood, or to a partial relaxation of the coats of the veins and a stagnation of blood within them. It has been also as universally supposed that all the evil results of this disease are owing to the accumulated or stagnated blood, while it is in the highest degree probable that neither the enlargement of the veins, nor the increased volume of blood within them, is productive of a single morbid phenomenon (5 748).

790, a. The enlargements of veins which are produced by ligatures, hanging, reflux of blood, and as presented in the "circuitous circulation" occasioned by the pressure of tumors or obliteration of the trunk of a vein, are in no respect instances of venous congestion, although they are generally adduced as the most palpable examples of that disease. Nevertheless, the stimulus of distension arising from pressure on a vein may give rise to the sub-acute disease which constitutes essentially congestion, varix, and venous hypertrophy; as set forth in my former Essay.

Four mechanical hypotheses have been surmised, to meet the exigencies of all cases. One of them supposes, that, during the cold stage of fever, the blood being determined from the centre to the

circumference, accumulates about the heart, and then regurgitates throughout the venous system of the internal organs. A second is similar in principle. It supposes that, at other times, the accumulation results from a simply diminished energy of the vis a tergo, which is inadequate to the maintenance of a free circulation, and that an accumulation of blood takes place in the veins as a consequence. A third hypothesis assumes that an embarrassed circulation takes place in the lungs, by which an obstruction is constituted to a return of blood to the heart, when, also, as a farther consequence, the blood accumulates in the veins of other parts, particularly the head. The fourth hypothesis has a similar mechanical cause. It imagines that venous congestions in all parts are owing to obstructions occasioned

by hepatic disease.

I have shown that the objections to all the foregoing suppositions are numerous and conclusive. In respect to those of a general nature, which are mostly applicable, I may now say that it is obvious that the blood would accumulate principally about the right cavities of the heart alone, and not in the veins of distant organs. Or, should a reflux happen, it should be coextensive and equal in the veins of all parts at equal distances from the heart. On the contrary, however, venous congestion is limited to particular parts, often to one organ, which may be, also, distant from the heart or supposed centre of obstruction. It is often, for example, the brain only that is congested; where, too, accumulations of blood, unless from disease of the venous parietes, would be prevented by gravitation alone. Again, also, were there any foundation for these hypotheses, the liver, stomach, kidneys, lungs, &c., should always be congested whenever the brain is the seat of the supposed reflux of blood. It is also obvious that, the moment an equilibrium is restored to the general circulation, as in bloodletting, the volume of blood should be equally reduced in the veins of all parts. Contrary to this, however, the veins of some particular organ or organs often continue in a state of great enlargement, as in the brain, &c.; while the central accumulation of blood, the supposed cause, is now completely removed.

790, b. So indefinite has been the pathology of venous congestion, that injuries attendant on falls, and those prostrated states that are induced by the shock of surgical operations, have been regarded as identical with profound congestion; and this even by so distinguished and able an observer as Dr. Armstrong. This great error in theory may explain his commendation of stimulants in aggravated forms of congestive fever, and is probably one of the causes which have led to their more indiscriminate use in less prostrating conditions of the dis-

ease (§ 970).

791. To arrive at the true pathology of venous congestion, as well as to ascertain the powers which circulate the blood, it was one of my primary objects to show that the state of the circulation in congested veins is exactly the reverse of the foregoing supposition (§ 790); that is to say, that the veins are in a state of active dilatation, and that the blood circulates freely within them. (See Comm., vol. ii. Also, § 382-394.)

792. I have shown, also, that the veins are susceptible of active dilatation in their natural state from the local irritation of stimulants; and that it is owing, primarily, to this action of the veins that they swell when the hand is immersed in warm water or exposed to a fire From these premises, I passed on to a demonstration that the veins possess an exquisite relation to the communicating arteries, of a sympathetic nature, and by which they dilate actively in obedience to the action which exists in the communicating arteries, and the quantities of blood which may be transmitted.—See, also, § 387.

I endeavored to show, also, that when the veins become inflamed, as in acute phlebitis, or in the sub-acute state of venous congestion, the inflammation of their coats acts as a stimulant, and thus occasions

an active dilatation.

793. Whatever, therefore, will produce any degree of inflammation in the venous parietes, will be a remote cause of dilatation; and, although the phenomenon depend upon that physiological constitution of the veins which occasions their active dilatation when increased quantities of blood are transmitted from the arteries, or when they are irritated by simple stimuli (§ 387), there is a wide difference in the proximate cause of the morbid and the natural phenomenon. In the latter case there is simply an obedience to natural influences, and the phenomenon is therefore transient; in the former, the influences are morbid, and the organic properties altered from their healthy standard, and the dilatation, therefore, is also cotemporaneous with the disease, or until the vein becomes disorganized, as in acute phlebitis. In the natural state there is also an increased volume of blood constantly transmitted to the veins; in the morbid the increased volume depends upon the enlargement of the veins. And yet the morbid dilatation has the physiological constitution for its foundation.

The following example shows the operation of the natural principle. "Cooks," says Sir B. Brodie, "are subject to varicose veins. Why? If you put one hand into warm water, and the other into cold, you know that the veins of the former become dilated, and that

those of the latter will contract."

This is a clear illustration of the physiological constitution of the veins, both as to active dilatation and contraction. But it goes no farther. The dilatation is the result of the operation of a healthy vital stimulus, and depends, in part, upon a constantly-increased volume of blood which is transmitted from the arteries, as set forth in section In varix there is no such increased volume transmitted, nor in phlebitis, nor in venous congestion. The dilatation is also permanent in the latter cases, while in that of the cook it subsides as soon as the stimulus of heat is withdrawn. The illustration is, indeed, a contradiction of the intended philosophy, since cooks are not subject to varicose affections in their arms, which are alone, though constantly, exposed to hot water. And so of the glass-blower. It is nothing more than the phenomenon which proceeds from exercise, or febrile action, or even from the common forms of inflammation; though slightly modified in these morbid states of action. The example serves to confirm, also, what I have taught as to the physiological relations between the arteries and veins, and the instrumentality of a great principle in the circulation of the blood (§ 387).

The assumed analogy to varix in the foregoing example is a part of the common mistake of confounding the physical with the vital laws, and shows the untenable nature of all such positions. We relax dry, dead matter by soaking it in warm water. The water pen-

etrates the substance; and this whether warm or cold. But what would be the effect upon the cook if she take the hand from the warm water and place it with the other in the cold water?

794. The venous tissue is composed of three coats; the inner, which resembles considerably a serous membrane, the middle, which

possesses longitudinal fibres, and the external or cellular coat.

The inflammation is seated mostly in the inner coat. Contraction and dilatation are effected by the fibres of the middle coat; which, being longitudinal, are capable of producing contraction or dilatation with rapidity and uniformity over a great extent. This natural provision was necessary to the purposes of venous circulation, and to accommodate the diameters or capacity of the veins to the suddenly and constantly varying proportions of blood transmitted to them from Circulation could not be performed without it; since, if the dilatation of the veins were effected by the supposed mechanical distension of the blood when increased volumes are determined upon them by the arteries, the physical resistance of the veins would impede the transmission, and the subsequent progress of the blood. There would then be a want of harmony between the arteries and veins, which would constitute a fundamental defect in organization. Nay, more; this harmony reaches, also, to special modifications of the organic properties of the venous tissue, by which the veins are rendered sensitive to the varying states of the capillary arteries, and to impressions arising from the varying quantities of transmitted blood (§ 133, &c., 385).

795, a. Now, it is in the foregoing peculiar organization of the veins, and the special modifications of their vital properties, that all the remarkable phenomena of acute phlebitis and venous congestion have their foundation. The veins dilate actively when inflamed, because such is their natural function when impressed by stimuli, especially their natural stimulus, the blood. Their dilatation is permanent in inflammation, as that affection operates as a permanent stimulus; and irritability is permanently increased, by which the blood has,

also, a preternatural effect (§ 143, &c.).

795, b. From the exquisite development of their organic properties, the veins are extremely liable to inflammation; especially that subacute form which constitutes venous congestion. And whether their inflammations exist in the form of acute phlebitis, varix, or venous congestion, it is always diffuse, extending rapidly over the venous tis sue, and liable, in all its forms, especially of phlebitis and congestion, to give rise to great constitutional disturbances. The diffuse nature of inflammation is partly owing to the natural principle by which the venous tissue has an associated action over an extensive surface; and all the local and constitutional phenomena may be traced to the peculiar vital constitution of the veins (§ 151, &c.).

Turning, however, to the arterial system, we find all things quite the reverse, and referable to the natural vital constitution of those vessels (§ 149, &c.). The arterial tissue is very little liable to inflammation, the disease is always very circumscribed, and produces but little, or no constitutional effect (§ 140, 526 a).

796. It was an important object in my Essay on Venous Congestion to establish satisfactory analogies between acute phlebitis and venous congestion, and I extended the analogies to varix and venous hypertrophy; and in so doing, as well as by the specific facts, demonstrated the inflammatory nature of these last affections. The several conditions were thus brought to illustrate and confirm the common nature of their pathological cause. Nor was the necessity overlooked of showing the fallacy of the universal doctrine of the dependence of varix upon local obstructions to the venous circulation and stagnation of blood, nor of applying to practical uses the true pathology of varix (§ 350\frac{1}{4}). It was thus shown how it happens that tying, or dividing, varicose veins, is so often followed by active phlebitis.

Besides its never having been shown that any obstructing cause exists either in venous congestion, or in the early stages of varix, if any stagnation of blood arose from other causes, the valves of the veins should be closed, and a knotted appearance presented at the several points. Such, indeed, had always been the supposition in relation to the valves, till I proved it otherwise. While the blood circulates, the valves are necessarily open (§ 391).—Rights of Authors, p. 919.

797. Taking the most simple and subdued form of venous inflammation, and in its most local sense, we have a type of the whole by which we may ascend progressively upward till we reach the strongly-marked conditions of phlebitis, without losing a hold upon many striking analogies which assure us that the common feature is imparted by venous inflammation. When constitutional influences may not obtain, as in the ordinary conditions of varix, there are still present the dilatation of the veins, their long-continued, unembarrassed circulation, their ultimate disorganization, pain, soreness, liability to active phlebitis, &c., to establish the intimate relationship of varix to the highest grades of venous inflammation, and to throw a broad light over the common family, however they may be removed in degrees of consanguinity.

798. It is also an important practical fact, as well as proof of the physiological doctrine of venous congestion, that this affection often springs up in quick succession in different organs, and often manifestly as sympathetic results of each other (§ 525, a). The same is also partially true of active phlebitis. Apoplexies are often remotely owing either to irritation of the stomach, or to venous congestions of the liver. On dissection, we find in most of the cases a state of venous engorgement in the brain, which has been excited sympathetically by one of the foregoing causes. It is especially to hepatic congestion, connected with peculiar influences of external predisposing causes, and the law of sympathy which predominates in the venous tissue (§ 387), that we must ascribe the epidemic apoplexies which have been described by numerous writers from Hippocrates to our own times. And how absurd would be the conjecture that in such apoplexies there happens an epidemic mechanical obstruction to the venous circulation of the brain, and where, too, gravitation would prevent all accumulations of venous blood, were it not for the active, morbid dilatation of the veins!

799. My demonstration, also, of the essential contribution of the derivative or suction power of the heart to venous circulation brings into view another principle which must tend powerfully to prevent all accumulations of blood in the veins.—(Essay in Comm. Also, § 388-390.)

800. Passing over a multitude of facts which I formerly embra-

ced in the foregoing illustrative proof of the inflammatory nature of venous congestion, and varix, I may now appeal to morbid anatomy for a tangible demonstration of my conclusions. But this ground is too extensive and circumstantial for the objects of the present work; and it has been most amply explored in my former Essay. It is worthy of remark, however, that the blood often gravitates from congest-

ed veins of the liver after death (p. 725, note).

801, a. Let us, therefore, attend next to a more practical demonstration, which will be again resumed under the Philosophy of the operation of loss of blood; namely, the appropriate treatment of venous congestion, in its simple forms, and as complicated with idiopathic fever. There is no practical question of greater moment, none more likely to be decided by theoretical principles, and none where the therapeutical facts settle more conclusively the nature of the disease, and the principles which should guide the treatment.

801, b. The method of cure had been either empyrical, or without a sound principle to guide it, till my Essay was published. So far as the mechanical hypothesis has had its sway, it has led to nothing but error, suffering, and death; since, upon that ground, stimulants have

been the remedies.—Notes F p. 1114, S p. 1124.

Nevertheless, experience has led some of the soundest minds, as it has many in regard to the humoral pathology in its broad application, to disregard the dictates of hypothesis, and to depend upon bloodletting and other antiphlogistic means; and the result has proved that they are the only successful means. But there was little of this practice till the time of Armstrong, and even this philosopher yielded to the mechanical doctrine in those intense forms of the disease where loss of blood was most imperatively demanded (§ 4, 960, 961, 964 1005). Bloodletting was inculcated by the ancient masters.

Now, therefore, antiphlogistic means being the remedies for inflammation of other tissues, and stimulants, as in such inflammations, being pernicious in venous congestions, they concur with all other facts

in establishing the inflammatory nature of this disease.

801, c. By the guide of the pathology and principles which I have indicated, and as shown by the results of the best and the worst expecience, we apply ourselves to the work of cure with an intelligible object before us; nor are we harassed by doubts, nor fluctuate from experiment to experiment (§ 960, 1005). There is a specific object in contemplation, the only principal one to which our treatment should ever refer (§ 667, &c.), and we pursue it with steadiness of purpose, and without the alarm or those imputations of imbecility to a noble art which flow from the mechanical doctrine, with its associated visions of debility. We regard the sluggish mood of the will as constituting much of what otherwise seems a state of universal weakness (§ 487 h, 569, 743), and look, as in all other cases, with the calmness of an enlightened understanding, upon an insidious and powerful foe, since we know his ambush and his strength, and our own means of circumvention and defeat.

802. As to the incipient seat of venous congestion, I shall only now say, that farther observation has sustained the opinion which I expressed, and endeavored to enforce, in the *Commentaries*, that there is "much ground for believing that the inflammatory action begins in the capillary veins, and that it is subsequently propagated to their trunks."

Many grounds are set forth for the conclusion, some of which were of the nature of principles; such as the extent in which the venous system of organs is generally and simultaneously involved, &c. This also corresponds with what I have said of the natural function of these vessels in relation to the varying proportion of transmitted blood.

When the larger veins are the seat alone of accumulated blood. they are commonly isolated, as in varix. Nor does venous congestion affect the largest series; but it is commonly limited to some complex vital organ, where we are certain that the capillary veins are more highly endowed with the properties of life than in parts which are less instrumental in the great organic processes, and where remote causes, external and internal, may therefore operate with greater intensity, or any general derangement of the organ may develop in the venous capillaries the supposed morbid condition. The terminating series of the arterial system are the instruments of all the great vital actions, and of all diseases,—of venous congestion itself. Analogy, therefore, as well as the general office of the veins, and their anatomical and functional alliance to the terminating series of arterial vessels, show us that the organic properties of veins are more strongly pronounced in the venous capillaries than in the venous trunks. And yet they may be so modified that inflammation may run higher in the trunks than in the capillaries (§ 134, 387, 526 a).

803. Venous congestion often passes rapidly into inflammation of other tissues with which the congested veins may be associated; and both forms of the disease frequently exist together in the same organ. This remarkable fact of the ready passage of venous congestion into inflammation of other associate tissues grows out of the vital relations between the veins and arteries (§ 387). The mode of propagation, therefore, is by continuous sympathy* or by reflex nervous action. The presence of inflammation in the coats of the veins operates either directly or indirectly as a stimulus upon the communicating arteries, through the foregoing natural relations (§ 802), and thus becomes a sympathetic cause of inflammation in some other associate tissue. The nature of the irritation is strongly manifested in the violent pulsations of the abdominal aorta, and of the coeliac and carotid arteries, in hepatic and cerebral congestion; and, I may add, that this phenomenon alone would establish the vital nature of the whole assemblage of movements and results. It is the result of continuous sympathy.*

804. But, while the foregoing morbid action is taking place in tissues associated with the congested veins, an abatement of the congestion or venous inflammation is simultaneously going forward. This harmonious process involves, also, another beautiful exemplification of reflex nervous action. As soon as the supposed influence is established upon the capillary arteries of the surrounding tissues, a reaction of sympathy takes place in the veins, by which the morbid state is overcome (§ 143 c, 152, 524 c, 528, 657, 660, 905). Their contraction then follows, as a consequence, and "the balance of the circulation," as it is called by the mechanical theorists, is more or less restored. This salutary reacting sympathy which arises from the supervening diseases is a common phenomenon. Pulmonary affections, for example, will supervene by reflex action upon gastric disease, and simultaneously operate as a relief to the stomach. A part of this great and universal law is manifested by the operation of blisters, and sometimes,

^{*} Continuous influence of these Institutes (§ 129 c, f, 498 a).

when the artificial disease subsides, its abatement accelerates the decline of the natural affection, and thus exemplifies the law of reflex nervous

influence in its compound aspect (§ 733 e, 893, 905).

Inflammation of other tissues is also an exciting cause of venous congestion, and here, too, the primary affection is apt to subside when the sympathetic one has taken place; the philosophy being the same as in the preceding case (§ 6381).

Again, active phlebitis of the liver is not infrequent, preceded by symptoms of venous congestion, which has simply passed into the more active state, just as irritation of varicose veins will excite acute phlebitis.

805. With the farther object of illustrating the pathology of venous congestion, as, also, to ascertain the pathology of spontaneous hemorrhage, I have gone into a critical inquiry relative to the latter subject in two Essays embraced in the Commentaries, one of which is devoted to that investigation (vol. i., p. 371-384; vol. ii., p. 546-566). The subject involves some physiological and therapeutical principles of great moment; and so far as I have shown the general dependence of hemorrhage upon venous congestion, it goes with my other facts in establishing the inflammatory nature of the disease. As a preliminary step, I demonstrated by the observations of mechanical theorists, that the prevailing physical rationale is contradicted by their own facts; that it is very rare that ruptured vessels have been detected by the microscope, and that no vessels admit the transudation of their fluids till putrefaction has opened the way. I shall now only add, that I have variously shown that capillary hemorrhage is not only the result of a vital process, but is analogous, as had been supposed by Hunter, to that of secretion. Prominent examples occur in purpura hemorrhagica, in petechial fevers, in sanguineous apoplexy, hæmoptysis, &c. (§ 1002).

The effusion of blood is the result of a salutary effort of nature to relieve the venous inflammation (§ 732). The quantities of blood which are often poured out in this condition of disease, not only with safety but with relief, are perfectly astonishing, and such as would be fatal if imitated by art. We may, however, well take a lesson from nature as to this her antiphlogistic treatment of venous congestions, and pause over the administration of stimulants to revive the energies of powers when prostrated by an overwhelming load of venous inflammation, for the relief of which nature often snatches the cure from the hand of art, and astonishes the stimulant practitioner by a stupendous

and successful discharge of blood (§ 812, 1018, 1019).*

806. The influences of venous inflammation, in all its degrees, are very different from inflammation of other tissues (§ 140). The general circulation, for instance, is apt to be much excited in common inflammations; but in acute phlebitis, and in venous congestion, the influences are quite liable to be of a depressing nature, especially upon the general circulation. This is generally true when either form of the disease exists in its greatest intensity; and the phenomena of excitement obtain, more or less, when these forms of venous inflammation are less violent, or when on the decline.

Its morbific reflected nervous influences, whether it be acute or subacute, are of a compound nature; partly the exciting influences of inflammation when affecting other tissues, and partly the depressing effects which are peculiar to morbid changes in the venous tissue.

^{*} See Notes F p. 1114, Fr p. 1135, Gg p. 1138, II p. 1139.

These are the most visible results, though more profound changes take place. The predominance of these two manifest influences is generally on the side of the depressing effect, in the stages of full development; but, in what may be called the chronic state of venous congestion, the exciting and depressing tendencies seem more nearly balanced. An exception, however, should be made in respect to venous congestion of the brain, where the usual exciting influences of inflammation are commonly in the ascendant (§ 686 b, 974 c, 975). It frequently happens that a very decided hardness, incompressibility, and considerable fullness of pulse attend the chronic forms of hepatic congestion, and that there will be little other apparent constitutional disturbance, excepting as the stomach performs its office imperfectly, the bowels more or less torpid, &c., and that these cases may suddenly eventuate in a very aggravated form; especially if miasmatic fever happen to supervene. The character of the pulse then undergoes a very striking change; becomes small, accelerated, loses much of its hardness and incompressibility (§ 686 b, 688 d, e). A chronic state of hepatic congestion is often the forerunner of miasmatic fever, and one of its exciting causes; the local predisposition having been formed by the predisposing cause of the general malady (§ 665, 813).

807. The local phenomena, also, are apt to be obscure in all gradations of venous inflammation; and it is no unusual event for uterine phlebitis to terminate fatally without its presence having been suspected; till a post-mortem examination has revealed a disorganized state of the uterine and iliac veins, attended with purulent matter within the vessels. And, although it is not my purpose to enter into a detail of symptoms beyond what may be necessary to illustrate the pathology of venous congestion, and the general principles which I have in view (§ 800, b), it is still worthy of the practical remark, and as showing, also, the special constitution of the venous tissue, that its inflammations of every degree are apt to be unattended with much pain, or tenderness on pressure; excepting when in the form of varix, which is sometimes very painful, and often tender (§ 725, b). An absence of those common phenomena of inflammation of other tissues, and perhaps only a subdued state of some other of its striking symptoms, not unfrequently betray the unwary into a false security, or beguile him into the fatal belief that "debility" is the worst attendant.

808. Upon my theory, therefore, of the pathology of venous congestion, we see more and more an admirable concurrence between the morbid phenomena of that affection and the natural physiological manifestations of the venous system; and we arrive through the physiological data at a ready interpretation of the most difficult problems in venous congestion. By these data we are enabled to discover, also, why the veins of the external parts of the body are not, like those of the internal organs, subject to congestion, but rather to varix; and why, again, an acute inflammation of a large internal vein is often limited to a point of divergence (§ 133–152, 526, 576 d, 578 d, 579 b, 721, 722, 794, 795).

809. It is owing especially to the foregoing peculiarities of venous inflammation, that when complicated, either in its form of acute phlebitis or venous congestion, with idiopathic fever, it greatly modifies the phenomena of that disease; rendering it insidious, obstinate, and fatal (§ 651, 652, 722 c). It is always an attendant of the plague

yellow fever, typhus, cholera asphyxia, "black death," &c., and imparts to them much of their peculiarities, severity, and danger.

810. Venous congestion and acute phlebitis not only steal their march in ambush (§ 807), but often throw a mask over constitutional fever, or present their own characteristics as the prominent phenomena. Hence it is that when venous inflammation is artificially excited by mechanical injuries of the veins, or by irritating injections, the results are said to resemble those of typhus, or yellow fever. It was this illusion, as well as a radical defect in his physiological views, and practical observations, which betrayed Magendie into the experimental fallacies recorded in a foregoing section (§ 744).—Note S p. 1124.

It will be also observed that the experiments go to prove the dependence of many of the phenomena of typhus and yellow fever upon

the attending venous congestions.

811. The foregoing modifying influence of venous congestion upon idiopathic fever (§ 688 dd, 806, 810, 961, &c.) is one of the many clear demonstrations of the modifying effects of local disease upon the vital states of the whole system, illustrative of the manner in which it may bring all parts into harmonious relation with any changes which such local disease may effect in the blood, and which would otherwise prove morbific (§ 847, g). It shows, also, how the entire body may be rendered susceptible, through morbific influences, to the action of remedial agents which might be otherwise inert, and how, when those agents exert salutary effects upon the various parts that may be partially influenced by some local malady, the morbidly sympathizing parts may then become reacting sources of salutary impressions upon the more absolute seat of disease (§ 143, 149–152, 514 h, 638, 804.

Also, Med. and Phys. Comm., vol. i., p. 649, 653-655, &c.).

The reflex nervous influences of venous inflammation being of a mixed character (§ 806), are extended, also, over the phenomena of any coexisting membranous inflammation, as well as of idiopathic fever; thus presenting still farther, in their delicate shades as well as prominent characteristics, the complex results of different forms of disease, whether existing independently or in connection with each other, or offering a striking illustration of the natural modification of the properties of life in the different tissues and organs, of the manner in which morbid changes in any common disease correspond in peculiarities with the natural peculiarities of the vital properties of the tissue, and showing how reflex nervous influences exerted on remote parts correspond with the peculiar conditions now stated (§ 133-151, 191, 577, 578). It is also worthy of remark, that where venous congestion is complicated with inflammation of other tissues, it is apt to lessen the hardness and force of the pulse, and to modify the other symptoms which are usually attendant on the recognized form of inflammation. In congestive pneumonia, and epidemic erysipelas, for example, it so far disguises the usual phenomena of the associated inflammation, that practitioners are constantly betrayed into the fatal use of tonics and stimulants. These associated conditions supply, also, a good exemplification of the tendency of venous inflammation to maintain the pulse within a limited degree of that hardness and incompressibility which are often very strongly pronounced in inflammations of other tissues ($\S 638\frac{1}{2}$, 814, 1005 h).

812. Examples of independent, isolated forms of venous conges-

tion are constantly seen in the brain, especially of children and apoplectic subjects, in the liver, &c. (§ 790, a). But the most prominent instance occurs in purpura hemorrhagica, where all its phenomena may be studied, and where its inflammatory nature may be fully ascertained, particularly if not complicated with fever, or with inflammation of other tissues, but depending, immediately, upon ex-

tensive congestion of the veins (805, 1002 d).

813, a. Venous inflammation in the form of congestion is occasioned more frequently than inflammation of other tissues by the predisposing causes of idiopathic fever (§ 644, &c., 742, &c., 776, &c.). Congestive fevers and local congestions prevail, therefore, at the same time and places. Both may also prove exciting causes of each other (§ 712, 777, &c.). The local affection may exist many weeks, grow into a state of intensity without being suspected (§ 807), and finally give rise to an explosion of fever, which, from the mild ness of the predisposition, may not have happened but for the exciting influences of the local disease. The fever which ensues, though not a sympathetic, but an independent disease, aggravates the local congestion, and gives greater intensity to its symptoms; though both conditions may coexist for some time in great force and obstinacy without any prominent or alarming symptom. These cases are not uncommon, nor is it a rare circumstance, in such instances, for practitioners in good repute to stand appalled over a lifeless body where they had only a few hours before predicted an early convalescence; and if the morbid anatomist be summoned to the scene of disappointment, chagrin, and distress, he seeks in vain for his post-mortem pathology, and pronounces a malediction upon Nature, or upon the imperfections of science, or upon the imbecilities of art (§ 695, &c.). "Medical philosophy is a metaphysical subtlety, and it were a thousand times better to confess our ignorance than to give up our senses."

813, b. Since, therefore, miasmata are so extensively the cause of venous congestion, it is important to consider that its exact pathological character will depend, cæteris paribus, like that of fever, upon the exact nature of the miasma (§ 653). Hence, also, the constitutional modifications of fever by venous congestions will be more or less determined by the exact pathology of the venous disease, as well as by the general effect upon the system of the miasmatic agent (§ 644,

&c., 722 c).

814. The considerations which have been now made enable us to understand the sources of those numerous modifications which distinguish the different species of fever, and aid, especially, our comprehension of their connections with venous congestion, and the various modifying influences of this disease upon the constitutional affection. Depending greatly on the specific nature of their predisposing causes, the local, as well as the constitutional changes, being imbued in the several cases with the specific influence of these causes, and the general characteristics being determined, for the most part, by the constitutional affection, the incidental venous congestions impart yet another general resemblance among the congestive fevers; varying the whole from their simple type, and often more or less confounding the specific phenomena under a common aspect (§ 638½, 811).

It is upon principles which I have now, and at other times stated, that we may understand why the typhus of one country, or of one

season, has been, under equal circumstances of treatment, varied in its phenomena from that of another; why epidemic scarlatina and measles are more fatal than the simply contagious; epidemic erysipelas more so than sporadic; why the intermittents of Africa are more pernicious than those of other countries (§ 630 e).—Note Oo.

815. When venous congestion so far disguises the attributes of idiopathic fever as to present the constitutional phenomena of venous inflammation, there is no condition of disease which demands more imperatively enlarged views in pathology, a deeper scrutiny of symptoms, or greater moral firmness for its appropriate treatment. If danger be seen, it appals the timid, and prostrated voluntary power urges him to the fatal use of stimulants (§ 487, 4882, 569). Under these fearful, but common conditions, the presence of well-marked inflammation of other tissues contributes to the safety of the patient. Such inflammations, however undesirable in other aspects, tend to counteract, for awhile, the depressing influence of venous inflammation, to lull the imagination, which sees nothing but "debility," or "putrefaction," in the prostrated state of the circulation and of voluntary motion, and in itself sustains the powers of life under the influence of depletive remedies, which alone can cure; and gives the last remaining hope which may be inspired by the unaided vis medicatrix, but which may be speedily extinguished by tonics and stimulants (§ 662 b, 675, 686).*

816, a. Venous congestion, being mostly occasioned by miasmata, prevails in its local form simultaneously with congestive fevers, and independently of any apparent predisposition to the latter. In this simple condition the disease is most apt to affect the abdominal organs. Nevertheless, it is evident in many of these cases, that the system is also imbued with a predisposition to fever (§ 666). In a still more simple form it is common in cities; particularly south of the latitude of forty degrees. It seems then dependent, also, upon malarious causes. And when it is considered that the liver is especially the seat of venous congestion in the different forms of congestive fever, and that the veins of this organ are quite liable to acute phlebitis, and that the phenomena of each are often analogous, a very special proof is thus supplied of the correspondence of the pathological states (§ 390 b, 526 b,

803, 809).

816, b. Other causes of malign influence may be transiently no-The disease, for example, is generally an accompaniment of severe forms of scarlet fever, appearing then mostly in the liver and intestinal canal; when it is also badly modified by the predisposing cause of the more specific affection. Again, it often springs up as a sequel of scarlet fever; when it is also imbued with the lingering influences of that complaint, and presents obstinate and difficult problems for the practitioner. It is still the digestive organs that suffer its invasion; and now it not unfrequently leads to inflammatory affections of the peritoneum, or of the cellular tissue of the surface, which ends in dropsical effusions; or, as when coexisting with scarlatina, glandular swellings may suddenly supervene about the neck. This is especially true if the intestinal canal be often subjected to the irritation of mercurials, which are apt to be of a peculiarly morbific nature in scarlatina (§ 689, l). Gastric irritations in childhood are common causes of hepatic and cerebral congestions; and in many adults there is a constitutional predisposition to cerebral congestion which is * See NOTE S p. 1124.

apt to terminate in sanguineous apoplexy. Various kinds of poisons, animal and vegetable, healthy and morbid, give rise to venous congestions; each one imparting some peculiar shade of difference to the affection (§ 721, 722). Such is the case with the narcotic poisons, alcohol (in delirium tremens), hydrocyanic acid, the poison of dissection wounds, the wourari, &c. (§ 662, c).

All the foregoing causes, excepting miasmata, produce the local forms of venous congestion; which is therefore never complicated with idiopathic fever when proceeding from those causes (§ 653).

817. Looking back upon the attributes, the causes, the constitutional effects, and the morbid anatomy, of venous congestion, and considering what is yet to be said of its treatment (§ 961, &c.), we find a great amount of proof in favor of the vital doctrine which I have propounded as to the pathology of this disease. As in inflammations of other tissues, the causes are such as make their impressions upon the properties of life. We see, also, in like manner, even a greater variety of modifications of the phenomena, corresponding, also, with the special nature of the predisposing causes. We see the disease influenced by peculiarities of climate, habits, constitution, age, &c., and constantly arising with or without fever in some places, while it is rare in others. It affects the robust far more frequently than the weak; high livers, the sanguine, and especially tipplers, more than the temperate and other constitutions. We see it slaying the morbid anatomist, while its remote cause has been concealed in a wound which no microscope can discover. We see it springing up in the brain in obedience to the specific relations of many agents to that organ; narcotic poisons, alcohol, prussic acid, carbonic acid gas, &c. We see it coexisting with affections of a distinctly inflammatory character, as measles, small-pox, scarlatina, &c., always increasing their violence, and adding, according to the nature of the principal disease, to their fatality, as when complicated with idiopathic fever. Or, if it supervene on common derangements of other parts, those maladies are such as predispose to inflammation of other tissues. Nor has morbid anatomy detected a cause of obstruction, nor can reason surmise a cause for a single instance in the midst of the variety; but where, on the contrary, the variety alone of predisposing causes demolishes the whole fabric of the mechanical pathologists.

If we turn to active phlebitis, or admitted inflammation of the veins, we find it equally depending upon the predisposing causes of venous congestion, and both diseases often associated in the same organ, or presenting themselves together as complications of idiopathic fever, and often making demonstrations of the same phenomena. Shall we, therefore, in one case, impute the phenomena to a simple mechanical fullness of a limited portion of the veins, while in the other, we refer the analogous symptoms, and the venous enlargement, to a local disvease whose pathology is settled upon the broad basis of organic ac-

The treatment is yet in reserve as contributing largely to the comprehensive philosophy of bloodletting, and as demanding, more than any other disease, that summary remedy. Let us, therefore, study the pathology of venous congestion, as of inflammation, through the philosophy of the operation of loss of blood, and the analogies which are supplied by its effects upon all other inflammatory conditions;

nor, when deliberating upon these profound and important topics, let us neglect the coincidences in the adverse effects of tonics and stimulants.

818. I now dismiss the great subject of venous congestion; than which none greater can undergo the attention of the philanthropist or the medical philosopher. But he may not bring to its investigation any fancied analogies, nor any of the laws, or other conditions of the inorganic world. He must start with all the philosophy of organic life, carry it all into the depths of the subject, and finally try the grand result by the test of therapeutical principles. He will then have found that he has accomplished a study of the most elaborate character, and where medical philosophy is presented in its most difficult but elevated aspects. He will have cleared up the way to all other obscurities in medicine, and have obtained a key by which he will acquire a ready access to most of the arcana of organic beings.

REVIEW OF THE PHILOSOPHY INVOLVED IN THE FOREGOING DISCUSSION OF THE REMOTE AND PATHOLOGICAL CAUSES OF DISEASE, AND OF THE SPECIAL CONDITIONS KNOWN AS INFLAMMATION, FEVER, AND VENOUS CONGESTION, AS IT RESPECTS THE NERVOUS SYSTEM.

818. Throughout the foregoing field I have endeavored to expound the operation of the remote causes of disease, whether of an external or internal nature, and of all remedial agents, which, in either case, exert their effects upon parts remote from the seat of their direct action, through the natural laws of reflex actions of the nervous system, and have endeavored to demonstrate variously modifying influences of those causes, and according to their special characteristics, upon the nervous power which is thus brought into a preternatural and alterative condition (§ 222-233\frac{4}{5}, 498-514, 894-905, etc.). Every distinct external cause we have seen to possess certain peculiarities, or as two or more may operate, and according to their individual or combined properties the nervous power will be modified and thus governed in its production or removal of discase, so far as this agent is concerned; and the same philosophy applies to those internal remote causes which consist of the various forms of local disease, or any other internal cause, such as the passions, when they exert morbific effects. In the former cases the effects depend upon reflex actions of the nervous system, by which the modified nervous power is brought into alterative action; in the other series of cases, or that of the passions, and diseases of the nervous centres, the development of the modified nervous power is not reflex but direct. The philosophy is, however, as I have shown, precisely the same in both cases, the only difference being that in the one, or that of reflex action, the sensitive nerves participate, while they do not in the other. The latter, therefore, I designate as direct action, or direct sympathy, the former as remote and contiguous sympathy, or, simply, sympathy. These terms, and sympathetic influences also, are wanted to express the functional influences of the foregoing processes, especially their morbific and therapeutical, and as being brief and comprehensive. The terms remote and contiguous sympathy were introduced by John Hunter, and predicated of the phenomena, and their import is perfectly understood, even by the community, and sympathy as far back as Hippocrates, and are exactly adapted to all that has been recently ascertained as to the nervous mechanism through which the function is performed, whether reflex or direct (§ 222-23334, 495-500 l, 500 o-514 m, 638 $\frac{1}{2}$, 894-905, etc.).

THE HUMORAL PATHOLOGY.

819, a. "To what errors have not mankind been led in the employment and denomination of medicines? They created deobstruents when the theory of obstruction was in fashion; and incisives when that of the thickening of the humors prevailed (§ 748, 789). The expressions of diluents and attenuants were common before this period. When it was necessary to blunt the acrid particles, they created inviscants, incrassants, &c. Those who saw in diseases only a relaxation and tension of the fibres, the laxum and strictum as they called it, employed astringents and relaxants (§ 569, b). Refrigerants and heating remedies were brought into use by those who had a special regard in diseases to an excess or deficiency of caloric (§ 433, &c.). The same identical remedies have been employed under different names, according to the manner in which they were supposed to the same identical remedies have been employed under different names, according to the manner in which they were supposed to the same identical remedies have posed to act. Deobstruent in one case, relaxant in another, refrigerant in another, the same medicines have been employed with all these opposite views; so true is it that the

mind of man gropes in the dark, when it is guided only by the wildness of opinion" (§ 4)

—Bichat's General Anatomy applied to Physiology and Medicine, vol. i., p. 17.

"Among physical people," says Hunter, "we find such expressions in common use as, the humors are affected in the bload; sharp humors in the bload; the whole humors being in a bad state; the whole bload must be altered, or corrected; and a variety of such expressions without meaning. They even go so far as to have hereditary humors, as gout, scrofnle Mer. and make use the merer to fee over humors attend that he hand had been seen to be a seen as the seen and had been been as the mean factor of the seen and had been been as the seen as the ula, &c.; and make us the parents of our own humors, saying that we breed bad humors. Humors are even supposed to gravitate to the legs slowly; and, in short, the whole theory of disease has been built upon the supposition of humors in the blood, or the blood itself be ing changed. I cannot conceive what is meant, unless it be that a strong susceptibility to a specific disease exists; as small-pox may bring on scrofula, or a strain the gout."—HUNTER'S Lectures on the Principles of Surgery, 11th.

Affirmative.

1. "Various animal poisons, such as those of the snake tribe, and different mineral poisons, as mercury, for instance, act upon the blood. Those derangements of functions and organs produced by the experimenter, when he introduces different deleterious substances directly into the blood, are likewise those that are produced by the sting or bite of certain animals; they are also those that take place in small-pox, measles, and scarlatina, of a malignant nature, as it is called. They are the same derangements that appear in persons exposed to putrid emanations, vegetable or animal, and to miasmata from the bodies of other persons that are themselves diseased and crowded in confined places, &c. Lastly, they show themselves, also, in individuals whose blood is only imperfectly or badly repaired by insufficient or unwholesome diet.

2. "There takes place a vitiation of the blood by the commixture of deleterious substances; next, in consequence of such vitiation, an alteration of the functions of the nervous system; and, lastly, the blood that supports the organs, and the nervous system that animates them, having suffered a general injury, a constant, though not al-ways appreciable, modification of these organs in their functions, or in their texture.'

3. "Diseases, resembling many of the preceding (no. 1) in their symptoms, or in the appearances discovered after death, are not unfrequently occurring where no delete-rious substance has been introduced into the blood, and in which there is no direct proof that any alteration of that fluid has been the primary cause of the morbid phenomena. Here, as in the preceding case (no. 1), it appears that the primary cause of the disease should be referred to the blood, which in this

Negative.

4. "The VITAL FORCES appear to be affected primarily by a great many poisons, by the vegetable or animal emanations, known by the name of miasmata, and by various modifications of the external agents which are incessantly acting upon us, such as a want of due exposure to the sun, too damp an atmosphere, and an unwholesome

5. "In every disease not immediately produced by external violence, the symptoms that occur depend either on a lesion of the forces that animate every living part, or on a lesion of organization (§ 177, 189 b). The former is primary and constant; the latter is secondary, variable in its nature, and inconstant in its existence."

6. "No one solid can undergo the slightest modification without producing some derangement in the nature or quantity of the materials destined to form the blood, or to

be secreted from it."

7. "Until it is PROVED that the forces which, in a living body, INTERRUPT the play of the natural CHEMICAL AFFINITIES, maintain a proper temperature, and PRESIDE OVER the various actions of organic and animal life, are analogous to those admitted by natural philosophy, we shall act consist-ENTLY with the principles of that science, by giving distinct names to those TWO KINDS FORCES, and employing ourselves in calculating the DIFFERENT LAWS they obey.

"The qualities of pus are modified by every alteration, whether physiological or pathological, which takes place in any other organ, even though it have no particular connection either of function or tissue. Thus, we have all seen instances of the pus secreted by the surface of a sore becoming suddenly altered in quantity and quality

case, has altered its nature under the influence of a simple moral emoence of unknown causes, as it has in the others, in consequence of the commixture of
various substances."—Andral's Pathologithere are certain constitutions, certain idiothere are certain constitutions, certain idiosyncrasies, which modify the qualities of pus, and in which it constantly assumes a peculiar and determinate character."—An-DRAL'S Pathological Anatomy.

819, b. I have thus brought into contrast the prominent doctrines of the distinguished individual who enjoys the honor of having restored the humoral pathology, with the same intentions that led me to a similar display of the chemical philosophy in its applications to physiology, pathology, and therapeutics, according to the exact quantitive method of the laboratory (§ 350, $350\frac{1}{4}$, $350\frac{1}{2}$, $350\frac{2}{3}$, $350\frac{3}{4}$ a-gg, 438-442, 447 f-448 f). I have done this, I say, because of the general alliance of the whole philosophy, and its almost universal sway in Great Britain and France, urged on by the powerful influence of the Parisian School, of the British Association for the Advancement of Science, of the British and Foreign Medical Review, the Medico-Chirurgical Review, the London Lancet, and other periodicals of less importance (§ $5\frac{1}{2}$ a, 349 d, $350\frac{3}{4}$ k, kk, 709, note). In considering the causes which have led to the subversion of medical philosophy, we should steadily distinguish the projectors from those who give the impulse and who govern public sentiment. It will be readily seen by every discerning mind, from my analysis of doctrines, and from what I have shown of the absence of all method, of all consistency, and the manifest want of any definite conceptions, in the chemical and physical doctrines, from the intermixture of vitalism, solidism, chemistry, humoralism, mechanical philosophy, &c., as the basis, individually and collectively, of exactly the same laws, that if the systems which are thus projected had been permitted to address themselves to the reason of mankind truth would have enjoyed, at least, an equal chance with error. But, the opposing school decided that it should be otherwise; and nothing remains, therefore, to the few who have been thus overlooked in the haste, but to disarm, if possible, the adversary, and turn his own weapons against him. These weapons, in the phraseology of science, are facts, and upon his own "facts" the great questions at issue might be safely rested. The whole matter, indeed, must ultimately turn upon this species of evidence. The theories naturally follow. As the mind becomes enlightened about the nature of the premises, there will be no difficulty in distinguishing between the fair and the false in theory. medical philosophy, where so much is controverted, truth cannot be attained without a simultaneous survey of the ground-work of error as well as of truth; or if the latter take its chance upon its Heavenborn rights, it is sufficiently known that it cannot remain long in the ascendant (§ 1 b, $5\frac{1}{4}$ c).

820, a. I thought it an object of importance to examine the whole ground of the humoral pathology in the former work, which I had devoted to the high branches of medicine, according to the best of my humble efforts. I shall now rather invite an attention to what I have there presented, than enter again upon any circumstantial view of the subject. But, independently of the important objects set forth in the preceding section, the present work would be defec-

tive in its plan, should all regard be neglected for a doctrine sc widely embraced by the educated physician in common with the ignorant pretender, and so broadly opposed to the solidism which lies at the foundation of these Institutes (§ 1 b, $350\frac{1}{4}$).

Moreover, there was not extant, till the appearance of the Commentaries, any representation of the doctrines of Humoralism, excepting such as might be gathered from the writings of its masters,

or from disquisitions of a desultory nature by its opponents.

820, b. The restoration of humoralism is an impressive exemplification of the popularity of simple views when brought into contrast with systems of philosophy that concern profound institutions of Nature, since it unavoidably associates itself with that identical ratiocination which is the parent of empyricism, but which the more enlight ened party can only recognize as the offspring of ignorance.

The essential facts, however, which are relative to the great foundations of Nature, especially in her organic department, have been too familiarly known, and their laws too well comprehended, to admit of any important innovations in medicine that shall long retard its progress, or rescue the projector from a certain oblivion. The beaten path is the only road to usefulness and enduring fame; but to achieve the latter requires the patient toil of the botanist who looks for eclat in the discovery of an unknown plant within the environs of London. Enlightened genius attempts no other route. It is alone the ambition of narrow mind, or the conceit of genius in its limited observation, that aspires at revolutions in philosophy. Hence the desertion, by the former, of that path for the old by-ways which lie obscured in the mists of antiquity; while the latter strikes out systems of such eccentricity as command, for awhile, universal admiration (§ 350, 350 $\frac{1}{4}$, 350 $\frac{1}{2}$).

820, c. Without, however, attempting now, as on a former occasion, to assign more extensively the ground of the foregoing conclusions, I shall briefly add that I know of no recent attempted innovation upon the philosophy of organic nature, whether under its healthy or morbid aspects, and as that philosophy recognizes the principles of vitalism and solidism, but has prevailed more or less at former eras, and has been so abandoned and eradicated that it now comes up again with the interest and power of novelty. And it comes to us again without having changed in one essential aspect its old thread-bare livery. That this should be so is owing to the absence of all efforts to refute the errors, excepting as transiently made in the form of opinions, and imbodied in the perishable journals of the day.

821, a. The humoral pathology having higher pretensions, from its dignified relations to the past, than its kindred hypotheses, should always secure for itself a patient hearing, and a full refutation (§ 1 b.

3501, and Rights of Authors, p. 919, no. 21).

821, b. In the brief review which I now propose the question should be first settled as to the main doctrine of the present humor-This was so accurately done in my Essay on the Humoral Pathology that the Medico-Chirurgical Review, which was addicted to that Pathology, quoted my exposition of the main principle, and allowed that it was "fairly stated." The following is the passage:

"The question at issue is not, whether the blood becomes diseased by a morbid action of the solids; and the solidist is surprised that the

defense of humoralism should often turn upon labored attempts to prove what every body admits. Nor is it, whether vitiated blood, or putrid matter, will excite disease when injected into the veins. The question at issue is, whether foreign morbific causes, and remedial agents, in their ordinary modes of operation, produce their primary effect upon the solids or upon the blood, and the latter become the cause of disease in the former; whether we 'have hereditary humors, as gout, scrofula,' &c., and whether we are 'the parents of our own humors, and that we breed bad humors," &c .- Med. and Physiolog. Comm., vol. i., p. 636.

In the same Essay I have quoted many recent authors, as setting forth the doctrine in exact conformity with its ancient impurities, and as promulgated in the newspapers of the day. A paragraph embraces all that is essential in the science of medicine; or, should the facts, the basis of the science, form an accompanying part, the whole is comprised within a moderate pamphlet entitled "Organic Chemistry in its Application to Physiology, Pathology, and Therapeutics." 821, c. It may be interesting to some should I annex the precise

modus operandi of morbific agents, as expressed in almost every work, ancient and recent, which recognizes the humoral pathology. The learned and distinguished Dr. Hosack shall speak for the school and

its imitators. Thus:

"That 'a little leaven leaveneth the whole lump' is as true in fevers as in making bread, or in the conversion of acescent fluids into acetic acid; and that upon the same principle of assimilation. That one spoiled herring will taint the whole cask, is well known to every housewife or fish-monger. Hence the great care of the Dutch in their herring fisheries to salt down their fish as soon as they are taken. They never permit the sun to rise upon them" (§ 830, b). And so, also, the chemists (\S 350, nos. 44, 45).

Although, as will be seen by the references, the exact chemical school differ from the foregoing in respect to the modus operandi of the mind and passions, they agree as to the physical agents; even to the Dutch herring (§ 349 e, 350, no. 44, &c.). So far as these illustrations go, it must be in justice admitted that they are peculiar to the walks of science, and are the rightful trophies of "experimental phi-

losophy." "Qui meruit palmam," &c.

In connection with what I have now said should be taken the details of the philosophy as expounded by its late restorer, which may be seen in the introductory matter, and in subsequent sections.

Such, then, by universal admission, is the philosophy of humoralism; and that it has no better foundation I have endeavored to demonstrate

in my former Essay (§ 4, b).*

822. On the other hand, what says the solidist? He tells us that, however simple the foundation (§ 638), disease and its cure depend upon the most intricate system of laws; far beyond any thing in the inorganic world: That these laws are associated with properties which are peculiar to organic beings, and determine all their natural processes: That all morbid conditions consist essentially in alterations of the properties and functions of the solid parts: That alterations of the blood are only consequences of these essential changes: That all practical medicine consists in restoring these solids to their nat-

* The philosophy and illustrations (including "the stimulating plan") remain unchanged, 1860.— Fide the late and standard British works of F. W. Headland, R. B. Todd, and J. H. Bennett. Also, notes p. 462, 872.

ural state, without reference to the existing condition of the blood, excepting in the aspect of symptoms: That it is only through the agency of the renovated solids, whose morbid state had affected the condition of the blood, that this fluid can be in any respect diverted from its modified conditions, or restored to its integrity.

Finally, we are told by the solidist that medicine, in any one of its

branches, cannot be taught in the compass of a pamphlet.

823. There are some eight or nine principal positions taken by the present humoralists in the way of tangible proof. With the exception of the second following, they are the same as are disseminated in the books of the older writers. They are now, for the first time, condensed into a methodical order from extended disquisitions in the Commentaries; namely:

1. That substances deleterious to life have been known to be taken

into the circulation through the lacteals (§ 826).

2. That gaseous and fluid substances, having an affinity for each other, permeate and unite through a dead animal membrane (§ 827).*

3. That morbific agents, when inserted in wounds, give rise to dis-

eases in various parts (§ 828).

4. That injections of various substances, and morbid blood, into the circulation, produce disease in the solids, and occasion death (§ 830).

5. That when many substances, as salt and acids, are mixed with the blood out of the body, they affect its sensible character apparently like the changes which happen to the blood when circulating in the

living organism (§ 832).

6. That when certain substances, such as yeast, are added to dead organic compounds, like vegetable infusions and dough, they create an intestine commotion. The example of a purid fish, which is of the same nature as the preceding, contaminating a barrel of sound ones, has been lately, as formerly, adduced in high quarters to prove the soundness of humoralism (§ 833).

7. That the blood, in certain conditions of disease, undergoes changes in its appearance; especially in refusing to coagulate, and in being of a dark color; and that chemists, also, have sometimes detected a va-

riable composition (§ 834, p. 780, § 1029).

8. That morbid changes occur in the secreted and excreted products (§ 835).

9. That diseases are transmitted from parent to child (§ 836).

10. That remedial agents, when injected into the circulation, sometimes produce the same effects upon particular organs as when administered by the stomach (§ 837).

11. That certain vegetable tonics, containing an astringent principle, will increase the physical strength of dead muscles, vessels, mem-

branes, &c. (§ 842).

824, a. So far as my knowledge extends, the foregoing admitted facts constitute the entire foundation of humoralism; and it will be seen that not a single one of them has any sound relation to physiol ogy! But what do they prove? Nothing whatever beyond the simple fact affirmed by each proposition ($\S 5\frac{1}{4}$). No one of them has the least bearing upon the questions relative to the natural operation of morbific causes, nor of remedial agents when employed according to the only methods that are sanctioned by nature or by art. We have also before us a remarkable display of the general habits of mankind

^{*} By a violent process it may be done through a fiving one.

in respect to the value of evidence in that sense which Nature has ordained as the basis of her institutions. Here we see nothing but a factitious assemblage of analogies for the foundation of great principles in medicine, devised by those very philosophers who condemn all conclusions in this science that are predicated, in other systems of philosophy, of those analogies which are impressed upon the face of Nature. Nor is it less worthy of remark, that the school in chemistry, who aspire at more exact applications of analogy to the healthy and morbid processes of the living being, borrow the whole from the inorganic world, and, for its better success, condemn this method of induction as employed by the vitalists in their study of organic phenomena.

824, b. Most of the foregoing premises in humoralism are brought into view in various parts of this work in their appropriate relations to special principles in physiology, pathology, and therapeutics; and the subjects are too extensive for elaborate consideration. In the Essay embraced in the Commentaries they have been subjected to all the examination which farther experience and reflection would enable me to bestow.

825. Humoralism, however, has now become so generally prevalent, and is sustained by so powerful an array of "authorities," and as my own writings afford the only systematic view of the subject, I shall, for the advantage of the young inquirer, present such a condensed and connected statement of my grounds of objection as will enable him to comprehend the misapplication of facts, and to apply them in the manner which appears to have been ordained by nature (§ $5\frac{1}{4}$). I shall, however, introduce other facts and arguments, that they may be taken in connection with the former, and shall simplify the subject by adopting a method in conformity with the foregoing propositions (§ 823). But it will be my object to bring into view the great principles which bear upon the several specific statements, either directly, or by reference to other sections. These references, therefore, will form an important part of the investigation, as they connect it with various principles and facts in physiology (§ 639, a).

826, a. As to the first proposition, that substances deleterious to life have been taken into the circulation through the lacteals, I object, that the phenomenon is rare, that it has been mainly ascertained of certain mineral substances, and that these, as allowed by the chemists, are eliminated by the kidneys in from five to fifteen minutes after their absorption (§ 280). The lacteals, on the contrary, elect, with astonishing precision, the nutritive chyle, and reject the rest. This is due to the exquisitely-modified irritability of these vessels; just as has been seen of a like provision in the glottis, the pyloric orifice, and vessels which exclude the red globules of blood (§ 191, 192). Nor can we too much admire the Wisdom which embraced in one universal Design the general good of the organism by so endowing the lacteals that they shall exclude all things which are not in harmonious relation to the special vital states of every other part (§ 274–295).

When such substances effect their entrance through absorbing vessels, it is, as we have seen, by modifying their irritability, and thus establishing relations with them; just as undigested food escapes a morbid pylorus, or the red globules of blood enter the serous vessels in inflammations. Bile, &c., are incapable of producing such modifi-

cations of the lacteals, and are, therefore, forever excluded. Here, too, morbific or remedial agents act in their concentrated state, and supply a ground for interpretation, through reflex nervous action, of the remote phenomena; while the little that may gain the general circulation is so diluted, and so soon excreted, as to be worthless in our

estimate of causes (§ 1089).

826, b. It should be also considered, that, notwithstanding the rapidity with which foreign matter at all offensive to the organism is eliminated by the excretory organs (§ 280), the blood and entire body may have undergone many renewals between the application of the predisposing cause and the explosion of disease; that hydrophobia may not supervene for months or for years, fever for a year or more, and may then return at annual periods; that salivation may follow a very minute quantity of mercury, and may be continued long after the saliva and other secretions have flowed in great redundancy, &c.; while, on the other hand, the interpretation of their modus operandi, according to the philosophy which I have propounded, is in perfect harmony with every principle advanced in these Institutes, and invites the severest scrutiny. In connection, also, with these topics should be considered all that I have expounded of the laws of sympathy, vital habit, constitution, acclimation, temperament, &c. As to the oft-alleged smell of garlic in the excretions, of the coloring matter of madder in the bones, or of the bile in all parts of the body, they are among the most attenuated of material substances, and are inoffensive to the lacteals and the general organism. (See, also, Med. and Physiclog. Comm., vol. i., p. 523-557, 576-581, 589-594, 599-608, &c.)

826, c. Nor should it be neglected, that there is no agreement among chemists as to some of the most important morbific and remedial agents which have been said to gain a ready admittance to the circulation.

826, cc. Why is the pulse always consulted in all forms of disease and after all remedies? Is it to find out how far the blood is affected, or whether the remedies be duly absorbed, or whether the heart or arteries be the seats of disease? Consider the unceasing modifications of the heart's action, and of the arteries too, as brought about by diseases of all parts, and by medicines, and by mental emotions, and mark the coincidences, and you will allow that you "feel the pulse" simply to learn the nature of the reflex nervous influences which remote diseases inflict upon the circulatory organs, and to thus find out the nature and force of those diseases, or equally in the case of medicine what reflex nervous influences they institute either mediately or immediately. If such, then, be our objects in feeling the pulse, why is not the same philosophy applicable when diseases spring up consecutively, or when morbific causes, acting upon surfaces, light up diseases in the internal organs? In the former cases you "feel the pulse" for the purpose alone of ascertaining the nature and extent of the disturbing or moderated reflex nervous actions, whether you know it or not, and in the latter cases the analogy is supported by all the pathological and therapeutical facts, and especially so by the staring fact that powerful irritants, like tartarized antimony, which occasion violent disturbances when conveyed into the circulation, break down inflammations and high arterial excitements when applied to the intestinal mucous membrane (§ 829, 902 g, 904 bb).* Why is the tongue, like the pulse, always expected to supply information as to the diseases of other parts and the

^{*} The universal custom of "feeling the pulse" is a remarkable example of an equal universal unconsciousness of the philosophy which relates to the subject.

salutary or injurious effects of remedies? Can any other rational solution be offered than that which I have presented in relation to the heart and arteries ($\$500 \ m$, $687\frac{1}{2}-688$, $694\frac{3}{3}$, 840, $891\frac{1}{2} \ k$, $892\frac{3}{3}$, 893)?*

826, d. We should not be led into the error of confounding the results of agents applied to the trunks of a nerve and to its extremities. The physical philosophers have taken advantage of the comparative failure of the former to show that morbific and remedial agents do not produce their remote effects through the medium of the nervous system, and have adopted this view from Müller's misapprehension of the subject. "The narcotic action of opium," says Müller, "does not react from a particular point of a nerve on the brain." Therefore, argue the materialists, when applied to the surface of tissues, its narcotic effect is due to absorption. But the great Physiologist has shown, himself, the error, while, at the same time, he proves the untenable nature of humoralism. Thus:

"The spirituous extract of nux vomioa, introduced in a small quantity into the *mouth* of a young rabbit, produces immediate death (in a second of time); whereas, when applied to a nerve at some distance from the brain, for instance, to the ischiadic nerve, it produces no

general symptoms" (§ 494 dd, 498 c, 514 d).

There is the broadest distinction between the trunk of a nerve and its expanded extremities in connection with organic tissues; while, also, the organic properties of the terminal fibres, and especially sympathetic sensibility (§ 201, 451 d), are incomparably more strongly pronounced than in the nervous trunks. The important consideration has been also neglected that two orders of nerves are concerned in the function of remote sympathy as it occurs naturally, and that the points of departure and of incidence are the expanded portions of the nervous system. This is also undoubtedly true even of the sympathies of the nervous system itself, which embraces all the elementary parts of other organs (§ 472, no. 4, 514 d, 516 d, 526 d. Also, Med. and Phys. Comm., vol. i., p. 507, 563-566).

Moreover, when irritating, or other agents, produce strong impressions upon the surfaces of organs, it is not, as supposed by Müller and others, mainly upon the ramifications of the nerves, but may be equally, at least, upon the organic properties of the other tissues of the part (§ 184, 188). Hence, particularly, the wide difference in the effects of irritants, &c., when applied to the trunk of a nerve and to an organ of a different vital constitution; as shown, for example, in the action of vesicants (§ 133, &c.). The insusceptibility of nervous trunks is also farther shown by their remarkable exemption from the

action of morbific causes (§ 526, d).

827, a. The second fundamental proposition of humoralism is in partthat gaseous and fluid substances, having an affinity for each oth-

er, permeate and unite through a dead animal membrane.

That fact is undeniable. But what is its physiological aspect? Is it worthy, in any other than its naked relations to chemistry, of grave consideration? And so of the entire amplitude of endosmosis and exosmosis. There must first be shown a correspondence between a dead, permeable tissue, and a living, impermeable one, before we can proceed to apply the foregoing fact in any physiological bearing. But its utmost latitude would only show that foreign substances unite chemically with the blood through the living tissues. It is true that,

^{*} See Notes I p. 1118, LL p. 1140.

more recently, active chemical agents have been brought to bear in a corresponding manner upon living tissues; but the violent influences which have been thus set in operation render these experiments as worth-

less as the original ones. It is equally a perversion of nature.

827, b. Of all the agents which surround us oxygen gas is the only one which has been shown, with any degree of plausibility, to penetrate a living animal tissue, or to unite chemically with the blood, or with any supposed constituent of that fluid. If it be allowed, also, that this has been demonstrated, nothing can be predicated of it analogically in respect to other extraneous matters, since it is an ordained function of organic life, under the control of specific laws in the animal and vegetable kingdoms, and conducted through special parts of the organism. The philosophy is the same as we recognize in all other parts. It is the office, for example, of the chylopoietic and sanguiferous organs to rearrange the elements of food, and endow the new compounds with the properties of life; while it is that of the glandular organs, the membranes, &c., to select certain constituents from the common homogeneous mass by virtue of these vital proper ties, and to impress upon them various peculiarities, according to the mechanism of each tissue, and as the vital constitution of each part may happen to be modified (§ 18, 42-44, 133, &c.).

Coming again to the specific uses of oxygen in the organic kingdom, the relative laws, the organs, the final causes, &c., are also different in the two organic departments, and even varied as to organization in animals; yet in all according to other variations in the general physiological constitution (§ 133-151, 185, 259-295, 409, 410).

But, I think it must be conceded that I have shown that there is no physical penetration of the pulmonary mucous tissue even by oxygen gas, and that the formation of carbonic acid within the lungs is primarily due to a strictly physiological process (§ 135, 419, 433, &c., $447\frac{1}{2} a-f$).—Notes N p. 1121, R p. 1123.

I am now conducted to a fact which illustrates the principle on

which miasmatic poisons operate.

It is well known that adult dogs, &c., will bear without injury a suspension of respiration for the space, at least, of five minutes. But they perish immediately if plunged into carbonic acid gas. Therefore, say the humoralists, the gas is absorbed in the latter case, which makes the difference in results. This, however, is contradicted, in the first place, by the ordination of nature that carbon shall be evolved from the lungs, and by an organization of the mucous tissue of the lungs corresponding to that fundamental law; whether the process be the result of chemical or vital actions, or both united (§ $447\frac{1}{2}$, f). Organization is thus specifically opposed to the absorption of carbonic acid. As well might it be assumed that gastric juice is resorbed by the mucous tissue of the stomach. Carbonic acid, therefore, does not destroy by absorption and union with the blood (§ 419, 420).

But this incontrovertible philosophy is sustained by direct experiment; since it was found by Nysten that "carbonic acid gas may be injected into the venous system in large quantities, without stopping the circulation, and without acting primitively on the brain; but when more is injected than the blood will absorb, it produces death by distending the heart, as when air is injected into the veins."-NYSTEN, Récherches, &c., p. 88. This, however, is not the modus operandi.

Here, then, we have the principle demonstrated, which is of universal application to mephitic gases, upon whatever surface their action may be exerted. The poisonous action of carbonic acid is exerted upon the pulmonary mucous tissue, and then only upon the brain, as a consequence of that primary effect, and through the physiological relations of the mucous tissue of the lungs to the great nervous centre (§ 129, 137, 222, &c., 666. Also, Med. and Physiolog. Comm., vol. i., p. 443, &c.). This lets us into the secret why certain poisons, as that of the viper, of the mad dog, and some others, have no action upon the stomach, or when applied to the surface of the brain, but operate with violence when inserted within the organization of the skin, and why that of the rhus vernix, &c., will affect the skin when applied only superficially (§ 135–137, 140, 150, 904 b).

Again, in connection with the foregoing illustration, it is an important fact that animals may be destroyed by the application, for a considerable time, of carbonic acid to the skin, although free respiration of atmospheric air be permitted. This shows that it may also exert a deleterious action upon the organic constitution of the skin; and by analogy, therefore, such may be more or less the case with malaria. And it should be farther stated, that the action of carbonic acid agrees, also, with that of concentrated forms of malaria in the instan-

taneousness of its effects (§ 654, a).

827, c. An almost endless series of examples of clear, definite character illustrate the philosophy of more obscure but analogous problems. Another, for instance, may be found in the effects of the nitrous oxide gas, when respired. Here, the immediate production of the phenomena, and more especially the abruptness with which they subside, prove that the whole action of the gas is upon the pulmonary mucous tissue, and that the general phenomena can be in no respect owing to a modified state of the blood, however the gas may be absorbed. And just so with the respiration of ammonia, which brings on coughing, rouses the circulation, &c., instantly, and which cease as instantly on removing the exciting cause. The example of cold in producing pneumonia, or rheumatism, &c. (§ 649 c, d, 657, 666), the fatal action of hydrocyanic acid, aconitina, strychnia, &c., the remedial influences of tartarized antimony, of the mercurials, and of numerous other alterative agents, concur in one general illustration of this subject (§ 494 dd, 550-563). The philosophy relative to reflex nervous action conducts us through all the labyrinth of the wide-spread influences that radiate from a given point which may seem almost alone exempt from the general invasion of disease (§ 222, &c., 500, 904 b, 1066 a).—Note M p. 1120.

827, d. The present place supplies a good opportunity for introducing a case of death from hydrocyanic acid; partly with a view to our present subject, and to serve, in part, as a reference to illustrate

other topics. Thus:

A medical gentleman had swallowed a fatal dose of Scheele's hydrocyanic acid, from which he died in about ten minutes. "On cutting into the right lung, a frothy, dirty-brown semi-mucous fluid exuded, tinged with blood. There was no odor of prussic acid from it. In the cavity of the right pleura were about eight ounces of thin serum. The left lung was firmly adherent in its whole extent to the costal pleura. Heart firmly contracted. It exhaled no smell of prussic acid Liver healthy. Spleen soft and easily broken down, resembling mul-

berry jam. Kidneys natural. The stomach contained about fifteen ounces of half-digested food, that gave out the well-known odor of bitter almonds. The mucous coat of the stomach healthy, and smelled strongly of prussic acid after the stomach had been emptied of its contents (§ 657). Intestines healthy. Vessels and sinuses of the brain filled with a dark-colored fluid blood. No smell of prussic acid. Blood every where fluid" (§ 494, 904 b).—Mr. Pooley, in London Medical Gazette, 1845.—See notes, p. 172, 863.—§ 1066, 1088 a, b.

827, e. The foregoing philosophy enables us to understand why the morbific action of miasmata is promoted by various causes which increase the susceptibility of the system (\S 663), and which has its parallel in numerous examples of daily occurrence; as the greater liability of mercurial agents to produce salivation if we increase irritability by cathartics, blood-letting, &c. (\S 556 c, 630 e); while, on the contrary, had humoralism any foundation, cathartics and blood-letting should diminish the chances of mercurial action, nor should that action increase long after profuse ptyalism has been established. The warm bath promotes the constitutional action of mercurial ointment by increasing the

susceptibility of the skin and system at large (§ 1088 b, c).

It should be observed, also, that upon the hypothesis of humoralism there should be no exemption of individuals from epidemic diseases, since the blood of all should be equally liable to contamination. Humoralism may not, consistently, assign as the ground of exemption a difference in the susceptibilities of the solids which have been induced by other causes (§ 651 b, 657 a, 837 b); and since, therefore, the blood is the pabulum vitæ, and convertible into the solids, it should, upon the humoral doctrine, when itself diseased, occasion universal disease of the solids (§ 663). The same is also true of the poisons, of the prick of a pin, &c.; but always affecting some severely, and others slightly,—the former sometimes striking at one organ, and again at another, while the latter induces in one man erysipelatous inflammation, in another always phlegmonous, and in a third none at all (§ 652 c, 828 c, 494, 740, 741).—Note Oo p. 1141.

827, f. If, however, it be admitted that offensive substances when absorbed operate through the medium of the circulation, solidism and vitalism can alone interpret the phenomena. There is abundant proof that the results are not due to any affection of the blood, but must be referred to the direct action of the agents themselves upon the vital constitution of the solids to which they are distributed. This construction of the subject, therefore, is directly within the pale of solid-

ism; though it be foreign from the truth (§ 284, 904 c).

827, g. Again, however, most of the substances whose presence in the blood or secretions can be detected (a) are either innoxious, or undergo chemical decomposition as soon as they come in contact with the circulating mass, and would therefore either be rendered inert, or would certainly give rise to different phenomena from those of the

agents in their original shape (§ 52, 149, 650).

827, h. But this part of the doctrine of absorption does not end with gaseous substances; since there are some distinguished philosophers who maintain that seeing is produced by the penetration of light to the recesses of the brain, where it gives rise to certain cerebral changes that result in vision; just as Liebig and his school suppose that all the operations of the mind are determined by chemical chan-

ges of the brain (§ 349 e, $350\frac{1}{2}$ n-q). By the analogies of Nature, therefore, we must conclude that, whatever gives rise to other sensations must be equally absorbed and conveyed to the sensorium commune,—the odor of plants, the undulations of air, the prick of a pin, &c. (§ 837, b). If this be frivolous it is not the fault of the logic.

828, a. The third proposition of humoralism sets forth, that when morbific agents are inserted in wounds they give rise to diseases in

various parts.

Here, then, we have something besides ordinary surfaces. "facts" which I have considered in the preceding propositions were evidently unsatisfactory to "experimental philosophy," and, therefore, a start has been given to absorption by inserting the noxious agents within the vascular systems. But, I have gone extensively, in the Commentaries, into the proof that in all the cases of this nature the agents have been either violently forced into the torrent of blood, or that their direct effect is exclusively upon the injured part, and thence by reflected nervous actions over the system. It will be also observed that in these experiments the agents are brought into direct contact with parts where the organic properties are most exquisitely developed and susceptible. The time of incubation (§ 666) may be from an instant, as with hydrocyanic acid and strychnia (§ 350½ p, 494, 743. 826 b-d, 827 d, 904 b), to a year or more, as with the cause of intermittent fever (§ 561, 657), or even to years, as with the hydrophobic virus (§ 547, 559, 560, 654-659, 500 o, 503, 506, &c. Also, Comm., vol. i., p. 496-506). As to the last, the virus can neither remain in the wound, nor circulate in the changeable body for months, or for It is either washed away from the former, or carried off by the latter.

Now all these cases are exactly upon a par so far as principle is concerned. The same influences obtain in respect to the hydrophobic virus as with those agents which destroy life as soon as they come in contact with the body. This is the work of the nervous power; just as it is when joy, or anger, or a surgical operation, or blows on the stomach, &c., kill in an instant of time (§ 227, 230, 234 e, 476 h, 509-511). The principle is the same as when the division of a nerve excites inflammation in the part to which it is distributed. And all this conducts us, at once, to a knowledge of the modus operandi of the poison of venomous animals in the following comprehensive case.

828, b. "I have seen," says Dr. Johnson, the late distinguished editor of the Medico-Chirurgical Review, "the ear of a rabbit exposed to the bite of a cobro de capella, with a pair of scissors kept across the ear, ready to cut it off the moment the bite was inflicted; yet the

animal died quickly in convulsions" (§ 234 e, 507, 827 d).

The foregoing fact corresponds exactly with experiments of a very different nature by Van Deen, Stilling, Budge, &c. (§ 494), and forms, with those, substantial grounds for analogical inductions. They may be safely considered of universal application, whatever the morbific

cause, whatever the interval of predisposition.

828, c. It is astonishing, too, with what rapidity certain morbific causes will establish inflammation, and thus lead to an almost instantaneous disorganization. Take another example from the venomous serpent, as related by Sir E. Home. He caused a rat to be bitten by a snake. It died in one minute. The cellular membrane beneath

the wound was wholly destroyed, the muscles separated from the ribs and from a small extent of the scapula. The bitten part was greatly inflamed.

Here the inflammation must have commenced in the region of the thorax at the moment the bite was inflicted. Absorption and distribution were, of course, impossible, and there is nothing but the philosophy which I have propounded of the nervous power that will in the least explain the phenomena in this and all analogous cases (§ 222, &c., 234 e, 503, 509). By the foregoing case we are also prepared to understand that hydrocyanic acid may light up venous congestion in the brain, although it destroy with equal rapidity (§ 827, d).

828, d. Finally, an elementary example of universal application to morbific agents, and illustrative of the nature of life, will supersede the necessity of farther comment upon the three fundamental propositions of humoralism as it respects absorption (§ 823). This example is of the same nature as that of the seton, farther on; but more open

to the understanding of all (§ 905).

It will be admitted that when inflammation is excited by the puncture of a lancet, it is not by irritating, or otherwise affecting the blood; but that all the attendant phenomena are due to an impression made upon the solids, and to their consequent morbid action. The inflammation, thus excited, may be extensively and violently propagated along the part, as in phlebitis, &c. (I specify a vein, as it is here the acrid injections are made, § 830); and it is but reasonable to suppose that the same condition is owing to a similar cause at one or six inches from the wound, as at the eighth of an inch.* No sooner, also, does the inflammation begin than reflex nervous actions may ensue; but as we have no morbific blood in these cases, we must look for some principle, analogous to that in which the local changes began, to explain the general derangement (§ 500, 711, &c.). All this will help us to the philosophy of analogous developments in diseases of reputedly humoral origin. But, besides the common effects of inflammation the prick of the lancet may convulse the whole nervous and muscular systems (§ 222, &c.). Nay, more, and greatly to our purpose, the inflammation arising from a wound will be variously modified in its character by the exact nature of the wound itself, and the kind of instrument or violence with which it is inflicted (§ 652, c).

If there be now added to the point of the lancet sulphuric acid, or the virus of putrid animal matter, of the small, or cow-pox, or the poison of the viper, of the wourari, &c., there will be many diversities in the general results of the several causes thus superadded to the mechanical, but strong resemblances in the local phenomena, and in the progress of symptoms. The specific products, also, as well as other circumstances, denote specific modifications of a common pathological state (§ 722, &c.). If, then, the mechanical irritation in one instance have acted directly upon the solids, is it not a proper conclusion from the progress and analogy of symptoms, that the several varieties of poison have done so in the others? It cannot be said that certain differences in the results imply a difference in the principle, since all these results, where life is sufficiently prolonged, are purely secondary, and will be admitted to be consequent on the morbid affection of the solids. But all the primary phenomena in such instances coincide with each other, and have the same order of development.

^{*} By continuous sympathy, or continuous influence of these Institutes (sec. 129 c, f 498 a).

If the poison of the viper destroy life with great instantaneousness. this is conclusive against absorption, and is exactly allied in principle to the fatal operation of a blow upon the region of the stomach, or of surgical operations which produce instant death, or of the prick of a

pin which is followed by tetanus (§ 494 b, 509, &c.).

828, e. There is an endless variety of analogies where disease is excited by agents of a mechanical, or even of a more negative nature; such as cold, heat, wakefulness, fatigue, &c., which, like the operations of the mind or its passions, in producing or removing disease, killing or curing, according to the exact nature of the intellectual process, that are applicable with all the force of the strongest analogies to show that in all other cases the same laws prevail (§ 188½ d, 527 b, 902 m, 905). The laws of reflex nervous action explain the whole.

829. "When we consider," says Pereira, "the peculiarities attending the hepatic circulation, and that all the remedial agents, whose particles are absorbed, have to pass through the portal vein,—the vein by whose branches the bile is secreted,—our astonishment is great that this secretion is not more frequently affected by the various medicinal

agents put into the stomach."-Pereira's Mat. Med., p. 92.

May we not, however, rather be astonished that the frequent exemption of the liver itself from all morbid effects, as well as the condition of the bile, did not satisfy our able author that the doctrine of remedial and morbific action by absorption is contradicted by the plainest

facts (§ 889, a)?

Our author, however, has been led into an important physiological error by Magendie's assumption that the veins, and not the lymphatics, perform the office of absorption; while in respect to any ingress of deleterious agents, it is mostly by way of the lacteals (§ 277). mitting, therefore, that the violent agents of the Materia Medica operate by absorption, they are first conveyed directly to the heart through the thoracic duct; and if "astonishment" be great in the mistaken case of the liver, how much greater should it be when we consider the realities of nature, and observe how often the exquisitely irritable heart remains unaffected when the most powerful irritants would be emptied into its cavities. Or taking the construction of our author, the effect upon the heart would be equally the same, since a large proportion of the portal blood is delivered at the same cavities. In either case, the irritants would exist in a state of concentration in the most irritable organ of the body compared with their dilution in other parts, except the lungs, as 1 to 50, or more. And yet the heart often remains undisturbed in its regular action after the administration of violent agents, while they are simultaneously healing, or inflicting disease on other parts. I present, therefore, this isolated fact as adequate in itself to a full refutation not only of the doctrine of morbific and remedial action by absorption, but, by the force of analogy, to that of the entire system of the humoral pathology. If embarrassing to the humoralists in the case of the inirritable liver, it is conclusive in that of the heart (\S 500 m, $638\frac{1}{2}$, 826 cc, 840, 1089, 487 a, 904 c).*

830, a. The fourth grand assumption of humoralism, as a part of its basis, is the production of disease and death by the injection of various substances into the circulation (§ 823). These injections are made upon animals, and their effects carried up to the natural morbific

causes which operate on man.

^{*} Diseases have their predisposing and exciting causes (§ 645), and no one supposes that the latter are absorbed. Why, then, the former?

Strange as is this analogical ground of induction, it is, nevertheless, the great bulwark of humoralism. The doctrine is thus set forth by

its restorer, M. Andral:

"Various animal poisons, such as those of the snake tribe, and different mineral poisons, as mercury, for instance, act upon the blood in the same manner as deleterious substances injected into the circulation." "Those derangements of functions and organs produced by the experimenter, when he introduces different deleterious substances directly into the blood, are likewise those that are produced by the sting or bite of certain animals; they are also those that take place in small-pox, measles, and scarlatina of a malignant nature, as it is called. They are the same derangements that appear in persons exposed to putrid emanations, vegetable or animal, and to miasmata from the bodies of other persons that are themselves diseased and crowded in confined places, &c. (§ 653). Lastly, they show themselves, also, in individuals whose blood is only imperfectly or badly repaired by insufficient or unwholesome diet" (§ 744, 819 b).

830, b. The order of results as stated by Andral, and as adopted by

all humoralists, is the following:

"A vitiation of the blood by the commixture of deleterious substances. Next, in consequence of such vitiation, an alteration of the functions of the nervous system. Lastly, the blood that supports the organs, and the nervous system that animates them, having suffered a general injury, there takes place a constant, though not always appreciable, modification of these organs in their functions, or in their tex-

ture" (§ 709, 740, 744, 821, 847 d).

831. Injections of noxious agents into the circulation of animals were made to an almost incredible extent centuries ago; and millions, I may safely say, have been repeated in later times. But they prove only two things,—their short-sightedness and inhumanity. They certainly do not show, in the least, that the ordinary causes of disease are taken into the circulation, nor do they produce those constitutional affections which are generated by the natural operation of morbific causes, especially on the human species. Their action is commonly upon the venous system; and if the reader will refer to my remarks upon phlebitis, he will perceive the reason for the conclusion of many experimenters that they have given rise to yellow fever, typhus, &c., in the brute race (§ 744, 810, &c., 1088 d).

These devices of art are very extensively considered in my Essay on the Humoral Pathology, where I have endeavored to show that they all go to the proof of solidism (§ 827, f).—In Med. and Phys. Comm.

832. For an examination of what I have designated as the fifth proposition in humoralism (§ 823), I must refer the curious reader to the

Commentaries, vol. i., p. 401-408, 431-451).

833. The sixth foundation is relative to the yeast and herrings; and the reader will probably be satisfied with the references to this subject which occur in § 821, c; otherwise, he may consult section 350, nos. 44, 45; and the Commentaries, vol. i., p. 417, &c.

834. The seventh fundamental assumption goes with the fifth, and the reader, by the references there, may satisfy himself of their degree

of importance.

835. The eighth bulwark of the doctrine is the important fact,—important to the solidist,—that morbid changes occur in the secreted

and excreted products. Nor is it less important in its philosophical and practical bearings upon the humoral pathology; since it is undeniable that it places the learned and the unlearned practitioner on common ground. Their pathology is the same; and what is affirmed in the following extract of the educated, in respect to their practical habits, every newspaper in the land assures us is equally true of the pretender in medicine. Thus the extract:

"The humoral pathologist neglects the study of visceral lesions, and when he turns his attention to the digestive system, he only considers its secretions, and not its actual condition, or the state of its sympathies. His sole purpose is to evacuate sordes, or to produce a flow of healthy bile, and to eliminate depraved secretions; and this he attempts without possessing any knowledge of the effects of disease of the digestive system on other organs" (Stokes Theor. Prac. Med.).

Professional humoralism assumes that these "vitiated secretions" are due to a morbid state of the blood, and not to perverted actions of the solids, which, in their ordinary state, give rise to the various natural products. And so the newspapers. Perhaps, however, the student may obtain some ideas to the contrary by consulting the following references (\S 42, 44, 53, 135, 220, 222-233 $\frac{3}{4}$, 284-292, 307, 314, 322-326, 327-331, 407-432, 452, &c., 500, &c., 512, &c., 674, 675, 686, 891 $\frac{1}{2}$ k, 893 a, c, e, 896, 900, 902 g, 904 bb, 905, 905 $\frac{3}{4}$, 1088.

836. The ninth ground of induction goes back to ancestral diseases; and assumes their transmission, by hereditary impurities of the blood, to succeeding generations. I have referred sufficiently to the philosophy of this subject in the present work (§ 75-80, 143-147, 220, 327-331, 559, 561-563, 591, 659, 666 b, 674), and more extensively, and in other aspects, in the Commentaries (vol. i., p. 464, &c.). I shall not, therefore, again encounter this part of the foundation; but cannot refrain from adverting to its pernicious effects in practice. One of its vague attendants is the doctrine of "poverty of the blood," and this, as practically applied to active conditions of scrofula, is a fearful scourge to the human family. The "enriching black meats," and the "sustaining cordials," which are every where commended to the subjects of phthisis, in its early stages, are the occasion of a greater mortality in one day than ever proceeded from the abstraction of blood in all diseases since medicine became an art (§ 620, note. Also, Comm., vol. ii., p. 608-634, "Pathology of Tubercle and Scrofula").*

837, a. Humoralism assumes, as its tenth fundamental basis which I have indicated, that remedial agents when injected into the circulation sometimes produce the same effects upon particular organs as

when administered by the stomach (§ 823).

Rarely has this experiment been tried on man, in recent times; probably in consequence of the mere transfusion of blood having been fatal, and interdicted by law, in former times. It is almost entirely limited to animals; when, as might be expected, the agents exert their effects mostly upon the venous system; "giving rise to scurvy, yellow fever, typhoid fever, &c., not to mention a number of other affections which I called into being before you" (§ 744, 709, 810).

The case in which Dr. Hale, of Boston, injected castor oil into his own circulation is a standing reference; but loses force from want of confirmation. What though, however, it rewarded the gentleman with a few moderate evacuations, I have never yet seen it affirmed by

^{*} See Notes F p. 1114, Мм р. 1141.

the advocates of operation by absorption that castor oil has been detected within the organism after its exhibition by the stomach; and we need not doubt that the experiment has been satisfactorily tried.

837, b. That certain articles of the materia medica which manifest specific relations to particular parts when administered by the stomach will exert specific effects according to those relations when injected into the circulation is clearly inferable from the first principles in physiology. If vomiting result from the mere action of tartarized antimony upon the mucous surface of the stomach, and purging from that of castor oil on the intestine, it should probably follow that the same results will happen when either of these, or analogous agents, are injected into the veins, and are circulating within the very organization of parts possessing superficially those relations to the same agents (§ 150). Each series of observations, however, stands independently by itself. The injections prove nothing beyond their own results. They can have no bearing upon the question of superficial action; and we may as well deny that croton oil, hellebore, elaterium, &c., act upon the skin when they produce inflammation of that organ as to deny the same local action upon the intestines when they increase their motion, augment their secretion, or inflict inflammation upon them; we may as well deny, I say, that we feel with the ends of our fingers, or assume that offensive odors, tickling the throat, warm water, and mental emotions, produce vomiting through the medium of the circulation. Humoralism must group the whole under one category, and must include all those varying susceptibilities which arise from habits and analogous causes as exerting their morbific effects upon the blood; for the moment it regards the solids as taking an initiatory step it opens a door for its own expulsion (§ 651 b, 827 c, 1088 d).

837, c. A great variety of examples might be adduced in proof of the repugnance of nature to the doctrine of humoral absorption as commended to our confidence by the experimentalist, and which equally confirm the vital theories of morbific and remedial action, whether the agents be applied to the mucous tissue or to the skin. What, for example, would be the condition of the acetate of lead, or the nitrate of silver, or sulphuric acid, were they absorbed from the stomach? Utterly changed, perfectly inert, on their contact with the blood. How, then, does sulphuric acid, or the acetate of lead, arrest the night-sweats of phthisical subjects? What disposition, I say, will you make of the universal effects of certain familiar substances applied to the skin; as the numerous preparations of mercury? How will you account for the well-known action of nitric acid upon the liver, when applied in the form of pediluvium? Interrogate the chemist as to the condition of all these things, and many other analo gous remedial agents, when he mingles them with the blood (§ 1088)

The experiments, therefore, have no tendency to prove the doc trine of absorption. On the contrary, they go to substantiate what I have said of the nervous power as the immediate cause of the remote effects, and the importance of duly considering the special modification of the properties of life in the different tissues and organs (§ 133-152, 227, &c.).—Note R p. 1123.

837, cc. But, after all, the foregoing experiments are worthless in a practical sense, since they have been made (unless in rare and unsuccessful instances) upon a very few individuals in health; and there-

fore prove nothing as to their action upon diseased conditions (§ 137, 143, 149, 150, 152 b, 156, 163, &c.). And, coming to the multifarious examples in which animals have been the subjects, they serve only to raise our astonishment that educated men can have imagined their applicability, in any sense whatever, to the profound problems of human maladies. The difference in constitution alone is conclusive against the supposed analogies. It is conclusive, indeed, against all such reasoning from one species of animal to another species, however apparently allied; since, in respect to the critical relations even of food, there is scarcely any certainty attending this inductive process, while the distinction in respect to the influences of morbific and remedial agents upon different animals is marked by every agent which is capable of making any positive demonstration. Some vegetable poisons, indeed, which are most destructive to man, and to many species of animals, are to others of the brute tribe wholesome articles of food (§ 18, 150, 191, 366, 447, 854 bb).

838. The natural adaptation of the various fluids of the body to the several parts with which they come in contact, and the certainty with which most of them produce disease in parts to which they are not naturally related, is conclusive that the blood cannot be medicated by any agents of sufficient power to act upon parts that are morbidly irritable, without often endangering every part of the body. The principle is of course the same as with the truly morbific agents; and, to be fully comprehended, the following references should be consulted (§ 133, 136, 137, 233\frac{3}{4}, 277, 494, 526, 826 cc, 829, 847 a, 889).

839. As with morbific, so with remedial agents. The philosophy is essentially the same (§ 151). May we not, therefore, take from Nature an important hint as to the mode in which remedies operate, and apply it analogically to the modus operandi of morbific causes? Does unaided Nature medicate the blood? Does she ever effect a change in that fluid without an antecedent change in the solids? Never. Does she not always restore the blood from its morbid states through the agency of the solids alone? How is it with smallpox, and measles, and other self-limited diseases? Art can do nothing to shorten their established time, or affect their regular progress. Nature accomplishes the whole. But I say, again, does she first renovate the blood (§ 858, 861)? We may imagine primary changes in this fluid as the cause of the morbid changes which befall the solids; but if this were true, then, ex necessitate rei, the restorative powers must commence and advance with the blood. In the natural cure, however, there is no agent excepting the solids to exert the slightest impression upon that substance; by which I thus demonstrate the dependence of the morbid changes of the blood upon those solids by which their subsequent removal is brought about.

840. Try the question by an infallible experiment. Apply the medicine to the organ affected; tartarized antimony, for example, to the brain in phrenitis, to the lungs in pneumonia. How absurd the proposition! Even in the primary action of remedies upon the stomach, and when disease of that organ yields to their operation, it is not alone from the direct action of the agents, but greatly so from influences of the nervous power reflected upon the mucous tissue of the

organ (§ 514 b, 516 d, nos. 6, 12, 657, 658).

Circulating within the organization, remedial agents of an irritating

nature exasperate disease far more certainly and violently than do cathartics when acting upon a highly-inflamed intestinal mucous membrane. This will be readily appreciated by all who have witnessed the stimulant effects of muriate of soda when injected into the veins of the dying subject of the cholera asphyxia. Simple as the substance, the scarce audible heart bounded under its influence beyond its natural vigor, and the whole vascular system instantly emerged from its sunken state into one of preternatural excitement, and long after the most powerful stimulants administered by the stomach would not awaken, in the least, the expiring sympathies of the heart, nor violent irritants applied to the skin rouse its circulation (§ 829).

Can it be entertained that pneumonia, or ophthalmia, or erysipelas, or furunculus, &c., are relieved by the transmission of the various substances, which may yield relief, to the very organization of the parts affected? And when vesication, and bloodletting, and mental emotions, are added to those, a medley is presented which defies assumption, but which is interpreted with consistency through the agency of the nervous power (§ 222-233\frac{3}{4}, 686 b, 872, 904 bb, 905).

841. In former sections I had occasion to illustrate the law of vital habit by certain effects of morbific and remedial agents; and what is there considered would appear to cover the whole ground of solidism and vitalism. Among the many illustrations is the complex example of the influences of tartarized antimony (§ 549-554, 556), which may now be continued with a more specific reference to the humoral pathology, as it will be in a future section to that of its modus operandi (§ 902, 904 bb). But now, as hereafter, I shall show its operation through reflex action of the nervous system (§ 904 bb).

I may say, then, that it is especially to my present purpose that the humoralist, as well as the solidist, is guided, in his repeated administration of the antimonial alterative, by its effects upon the stomach; since nothing can be more obvious to either than that all the remote effects depend upon the amount of impression which the remedy produces upon the stomach. It is not, therefore, quantity, but effect, gastric effect, which is regarded in the administration of this distinguished humoral agent (§ 826, c). The intense excitement of fever, or the violence of pneumonia, yields to the first nauseating dose of the antimonial, or if it only approximate that point of gastric irritation. The next, and the next, in unaltered doses, may fail of an equal ascendancy, while the fourth makes no resistance to the returning phenomena. But, if there be now added to the original twentieth or eighth of a grain only a fiftieth or thirtieth part, the phenomena are again subdued the moment that gastric influence begins. And in this way may we proceed, experimentally, by continuing the same, or increasing the dose, and find at each repetition that the general results will conform to the impression which is made upon the stomach, at its nearest approximation to a state of nausea; whatever the requisite dose,—however small, or however large (§ 556, 873, 904 bb).

Again, antimonials are more salutary when they can be borne in gradually-increased doses than where it is necessary to lessen a small dose from the beginning. The reason is this. In the first, or most advantageous case, the irritability of the stomach is not morbidly susceptible to the action of the remedy, but, on the contrary, obeys the law of vital habit in its diminishing influences upon the suscepti

bility of the vital states (§ 551, &c.), so that the stomach is not injuriously irritated; while, in the opposite case, the law of habit has its exactly opposite effect (§ 556), and the susceptibility of the stomach being morbidly great, and farther aggravated by the antimony, disease of this organ is more or less liable to set in as a consequence, and the object of the remedy to be thus defeated. In the mean time, it may be shedding abroad pernicious reflex nervous influences in doses of extreme minuteness. In a general sense, the best dose is just short of that which produces nausea; but, at other times, occasional nausea may be very salutary, and again, at others, a full emetic dose may overthrow, at once, a formidable condition of disease (§ $476\frac{1}{2}$ h).

The principle, though not the details, is universal. Its practical application is of the highest importance, and, unlike the hypothesis of absorption, may be in the hands of all (§ 481, 494, 828 b, 1088).

842. The eleventh foundation of humoralism, and the last in the order of arrangement (§ 823), is derived from the tan-yard. Thus,—animal tissues have their strength increased by immersion in astringent vegetable infusions; therefore, as many tonics are also astringent, they are taken into the circulation and give strength to the stomach and the system at large by the same process (§ 569 b, 904 d).

So much has been said upon the foregoing philosophy in the course of this work, that I should have avoided the present subject but for its incorporation into the basis of humoralism, and as I was desirous

of presenting the whole system in a methodical manner.

My own construction of the modus operandi of astringents is briefly set forth in my Arrangement of the Materia Medica, and will be extended in subsequent sections of the present work. But I would now propound for the consideration of the humoralist the modus operandi of cold, of ipecacuanha, of muriate of soda, and analogous agents devoid of true astringency, in arresting hemorrhage; or how vesicants and ipecacuanha often relieve redundant effusions from the pulmonary and intestinal mucous membrane, or how opium restrains all secretions (§ 890 b)? The force of necessity which applies to the answers will be very likely to extend its sway throughout the classes of astringents and tonics, and yield to the laws of reflex nervous action.

843. That nothing may be omitted which may serve to complete my analysis of humoralism, I may state what may be regarded by many as a twelfth fundamental ground; though it is only an induction from the general assumption that the blood is radically vitiated, &c., and the efficient cause of the morbid state of the solids. Its "black" color, as it is called, which appears in congestive fevers, scurvy, &c., is taken as one of the important evidences of its corrupted state; and when it refuses to coagulate, humoralism assumes that "putridity" has taken place. It will be thus seen that "putrescency" is only a corollary of the seventh proposition in my analysis, and sustained by the fifth (§ 823, 834). Liebig has gone scientifically into the subject (§ 350); and in the Commentaries I have endeavored to do justice to its merits (vol. i., p. 403-410, 418, 430-440, 442-460, 663-673). But, what is more remarkable than the rest, it is argued, that, because the blood ultimately becomes "black" or "putrid," it therefore takes the initiatory step in the morbid processes. It is also an important "fact" in the "experimental philosophy" of humoralism, that the color of this blood is changed to a vermilion hue by adding saline cathartics to

that which is abstracted; from which the conclusion is drawn that the same substances are taken into the circulation when administered by the stomach, and that they then and there change the color of the blood in like manner; which proves that the remedial effect is exerted upon that fluid. There is no doctrine in humoralism more strenuously maintained, and none in which the conclusions are considered more logical. It goes with the rest in representing the nature of the "experimental philosophy" which now lies at the basis of theoretical and practical medicine. Next to this are anemia, chlorosis and iron.*

844, Finally, an author of the olden times, writing in the palmiest days of humoralism, but not of the professional corps, in one of his sallies upon the vagaries of philosophy, let slip a bolt which de-

molishes every material fabric in medicine.

"All the world knows," he says, "there is no virtue in charms; but a strong conceit and opinion alone, which forceth the humors (moral ones), spirits, and blood, which takes away the cause of the malady from the parts affected. The like we may say of our magical effects, superstitious cures, such as are done by mountebanks and wizzards (§ 167 f, note). An empiric oftentimes, and a silly chirurgeon, doeth more strange cures than a rational physician. Nymannus gives a reason: because the patient puts his confidence in him, which Avicenna prefers before art, and all remedies whatsoever. 'Tis opinion alone, saith Cardan, that makes or mars physicians; and he doeth the best cures, according to Hippocrates, in whom most trust. So diversely doth this phantasie of ours affect, turn, and wind, so imperiously command our bodies, which, as another Proteus, or a chameleon, can take all shapes, and is of such force, as Facius adds, that it can work upon others as well as ourselves. How can otherwise bleareyes in one man cause the like affection in another? How does one man's yawning make another yawn?-one man's p-ing provoke a second many times to p? Why does scraping of trenchers offend a third, or hacking of files? Why do witches and old women fascinate and bewitch children, but, as Wierus, Paracelsus, Cardan, Mizaldus, Valleriola, Vannius, Campanella, and many philosophers think, the forcible imagination of the one party nerves and alters the spirits of the other? Nay, more, they can cause and cure not only diseases, maladies, and several infirmities, by this means, as Avicenna supposeth, in parties remote, but move bodies from their places, cause thunder, lightning, tempests; which opinion Alkiadus, Paracelsus, and some others approve of; so that I may certainly conclude, this strong conceit or imagination is astrum hominis, and the rudder of this our ship, which reason should steer, but overborne by phantasie, cannot manage, and so suffers itself and this whole vessel of ours to be overruled, and often overturned" (§ 167 f, note, 227, 234 e, 500 f, o, 509, 892 $\frac{3}{4}$, 1072). What a display is here of our direct nervous action!

845. Having now considered the grounds upon which the humoral pathology reposes, and how estranged from the institutions of organic nature, I shall proceed to offer the reader a condensed view of my argument predicated alone of the fundamental laws of physiology.

I propose showing by this argument, that the blood is neither a primary cause of disease in the solids, in virtue of its own morbid condition, nor an aggravating cause of disease when altered in its character by the morbid action of the solids.

^{*} See NOTE R p. 1123.

846. No one will deny what is affirmed by Andral, that every morbid change in the action of the solids is probably followed by some change in the blood. The influences from bloodletting often give rise to very remarkable and instantaneous changes in the circulating mass (§ 952, a-h).—See KRIEMER's expriments § 485.

I also agree with Andral, that any *primary* alteration of the blood, of a morbid nature, must, with greater certainty, produce disease of

the solids (§ 827, e).

The latter proposition is the basis of humoralism, and it is this which I now address.

847, a. There is a specious parallelism about the two foregoing propositions, of which humoralism has taken no little advantage. Both are conceded by the solidists, and humoralism draws its conclusions from both, just as has been seen of its principal data (§ 823, &c.). Its inferences involve the assumption that the blood and the solids sustain, reciprocally, the same relations to each other; when, in truth, the distinction is nearly as great as between an agent and the object acted upon. There is this difference, however. In the present case, in their natural state, the blood is the object, while it contributes to the support of the agent, and to maintain its action.

Were the blood, therefore, to become primarily diseased, it would then assume the same relation to the solids as any other morbific cause, and this the more so on account of its incorporation with them.

Now, observe the humoral premises, as laid down by Andral, and considered impregnable by all humoralists. It will be seen that the first is the very thing which is most denied in humoralism,—the ground of solidism itself; yet is it put forth for an unreflecting world. Thus:

1st. Every morbid change in the action of the solids is followed by

some change in the blood.

2d. Every primary alteration of the blood, of a morbid nature, pro-

duces disease of the solids (§ 846).

Therefore, say Andral, and other humoralists, every morbid change in the action of the solids is occasioned by a primary change in the blood. That is the logic (§ 843). But, we have seen that the two propositions are not convertible in a physiological sense, while they stand as independent statements, and in exact opposition to each other.

But let us reverse the logic, and then see how the case will stand. By the first of the premises, the solidist argues that all morbid lesions of the blood are dependent on primary changes of the solids. And this conclusion is justified by the strongest force of analogy. From the germ to the adult, all the results of organic life have their origin in organic actions. The nutritive fluid itself, from the time that organic actions begin, is universally conceded to be either directly or indirectly the product of these actions; and the only sense in which the blood can be regarded as an agent, is that of stimulating the solids so that they shall carry on the work of life and appropriate the blood to their own uses (§ 1087).

Here, then, we must steadily regard the true relation of one to the

other, in the farther progress of this inquiry.

Now, it is said that the solids, which give being and vitality to the blood, become, in their normal state, the subject of its morbific action; and, according to the premises of humoralists and solidists, when the solids are diseased, the blood undergoes disease in consequence.

If, therefore, diseased blood be originally the cause of disease in the solids, it must certainly maintain an ascendency over them. Moreover, the solids, in their turn, react upon the blood and increase the diseased state of that fluid, or the primary morbific cause; and, according to the admitted premises, every increasing degree of disease in the blood must be a cause of increasing disease in the solids. Thus would the blood and solids perpetually act and react upon each other; and since a morbid state of the blood, according to humoralism, is the primary cause of disease in the solids, and constantly becomes more and more diseased and morbific in virtue of the morbid state which it sets up in the solids, it is plain, if the doctrine of humoralism were true.

there could never be a recovery from disease.

It follows, therefore, I say, that the solids having been brought int, a morbid condition by their own natural stimulus, and their own means of sustenance, and the morbific state of the blood continually advancing, according to the admitted premises, every disease so beginning must necessarily terminate in death. For, again, in the first place, I have shown the absurdity of attempting the restoration of the blood to its natural state by any direct action upon it by foreign agents; and secondly, what I have thus shown an absurdity is a matter of universal admission, since it is conceded by all that the natural state of the blood is entirely dependent on a natural or healthy state of the solids. Nor can Nature, in her spontaneous cures, begin to restore the blood but through a primary recuperative act on the part of the NOTHING, THEREFORE, CAN MAKE HEALTHY BLOOD BUT THE HEALTHY ACTION OF THE SOLIDS. It is exactly with morbid blood as The restoration of one depends as with morbid bile, mucus, &c. much as the other upon an antecedent improvement of the solids. No humoralist medicates the blood to change the bile or mucus, per se.

847, b. As the foregoing doctrine is based upon fundamental laws in physiology, which admit of no "exception" (§ 284-288), it is manifest that, when the constitution of the blood is altered, or becomes diseased, in virtue of a diseased state of the solids, the blood thus altered is not an aggravating cause of disease in the solids. Indeed, should it become, under these circumstances, a direct morbific agent to the solids, the same philosophy would hold, the same effect obtain, as were the blood primarily diseased; since, as the blood is entirely dependent upon the solids for its healthy constitution, the moment it becomes a morbific agent to the solids, the latter will have lost a con-

trol which they can never regain.

847, c. The fundamental principles now stated might have been inferred from the final cause of the blood; since it would have been a radical defect in the animal economy, that a fluid which pervades so universally every part, which is intended for the growth and nutrition of the whole, which depends upon those parts for its being, and those, in their turn, upon the blood for their nutrition, and is at all times in subordination to the state of the solids in the natural condition, should receive a morbid impress from a part or the whole, which would not only defeat its great final purpose, but give to it an ascendency over those powers and actions to which it is entirely submissive, for the great end of life, in their natural state (§ 43, 277, 278, 303\frac{1}{4}, 303\frac{1}{2}, 322-326, 385, 409 f-i, 411, 422, 424, 449 a, 464, 638, 733 d).

There is an ever-varying adaptation of the state of the blood to

the varying condition of the solids, and this is brought about by the solids themselves. It proceeds, in equal pace, with the changes of the latter; as clearly and forcibly exemplified during the operation of general bloodletting (§ 136, 970 c). The properties and universal condition of the blood, therefore, undergo changes corresponding with any alterations of the vital condition of the solids. What is physiologically true in this respect must be equally so in a pathological sense (§ 639, a). A morbid state of the blood is an exact product of an antecedent change in the solids, by which they move on in harmony (§ 653, 733 d, 740, 741).

847, d. Just so is it with the morbid product of an ulcerated surface. The exact condition of the product will depend upon the exact state of the solids by which it is generated (§ 653), nor does the product, however morbid, increase the diseased state of the solids, unless it undergo some chemical change after its elaboration. Were it otherwise, the natural and immediate result would be a perpetual increase of the morbid condition of the ulcer and of its secreted product. The same, again, is exactly true of the blood and the organs upon

which it depends (§ 133 c, 136, 137, 150-152, 740, 741).

The analogy of which I am now speaking is still more forcible in its connections with the humoral philosophy of morbid blood, when it is considered that, with whatever violence morbid secretions may act upon sound parts, they bear a common relation to all other morbific causes, and that, therefore, as soon as the parts are brought into a morbid state and generate other or the same morbid products themselves, they cease to be offended by either. The surface upon which the syphilitic virus, or that of small-pox, excites suppurative inflammation, ceases to be offended by the virus as soon as it becomes the product of the part. Now it is, indeed, that not only is this resistance made, but Nature may set in with her recuperative process.

It is hardly necessary to add, that there is no physiological coincidence between the foregoing morbific causes and morbific blood in the humoral acceptation. The blood, in the humoral pathology, is converted into a morbific cause by agents foreign to the organic properties and actions. These properties and actions, I say, therefore, will have lost their control over the blood thus affected, since the blood is their natural stimulus, the pabulum vita, and depends upon a healthy

state of the solids for its integrity.

847, e. The correspondence of which I have now spoken between the modified vital properties of a part and its morbid products, and between a diseased state of the solids and blood rendered morbid thereby, has its deep foundation in physiological laws. The principle is seen, naturally, in the adaptation of the veins to venous blood, the ureters and bladder to the urine, of the gall-bladder and mucous tract of the bowels to the bile, while venous blood is fatal in the arterial system, and these natural products excite inflammation in other parts (§ 133, &c., 385, 733 d). Mark, however, that such inflammation cannot be overcome while a fresh supply of urine or bile is brought into contact with the parts which they had thus offended. It is not now, as was just seen of the syphilitic and small-pox virus (§ 847, d), since no part is capable of having its constitution so altered as to generate urine or bile, and therefore there can be no preternatural adaptation of the vital state of any part to the morbific properties of those natural secretions.

And just so with the ordinary forms of disease, if excited in the solids by a primary diseased state of the blood. There will be nothing, then, to make healthy blood, and disease must go on to the death. The humoralist seems to have had some vague conception of this,

since he applies himself to drugging the blood.

847 f. Again, as to the morbid secretions and the blood, in the former case the general powers of the body may contribute their restorative influence (§ 848), but not in the latter, according to humoralism. But, in the sense of solidism, if the alterations of the blood depend on an antecedent morbid state of the solids the changes of the blood will be always suited to the existing condition of the organic properties and actions, of which the morbid state of the blood has been only a consequence, as in the foregoing analogous cases (§ 847 e). And since the changes are thus exerted, the same organic properties and actions, whatever their condition, can, either unassisted or by the aid of remedies, replace, by their own improvement, the morbid changes of the blood by others of any degree of approximation to the healthy standard; as was seen of a part in relation to the syphilitic or small-pox virus.

847, g. Is it asked why the blood, when essentially altered by any local inflammation, is not, according to my principles, detrimental to the system at large? The solidist can reply upon sound physiological

laws, while the humoralist can make no answer.

I say, then, that all other parts are now modified in their powers and functions by reflex nervous influences of the local disease (§ 222, &c., 452, &c., 500, &c., 512, &c., 733 d, 811). In proportion as that affection is capable of modifying the blood, so does it exert a reflex nervous action upon all parts of the organization (§ 674, d). The modifications of the blood and the constitutional derangement being produced by a common cause, the blood and the solids are universally adapted to each other; the blood being thus inoffensive to the general organization, just as the virus of the small-pox is harmless to the

skin by which it is generated (§ 858).

This law of adaptation meets us every where, both in the natural and morbid states of the animal kingdom. It is the same great work of Design under all the circumstances of life. In disease it is coincident with what is seen in health of the modified irritability of the larynx, adapting it to atmospheric air, of the pylorus to chyme, &c. The same as the adaptation of natural bile to the natural state of the intestine, or of morbid, acrid bile to the diseased or disordered intestine. It is analogous to the expedient by which a deep-seated abscess reaches the surface, and, finally, to all the processes of recuperation (§ 156 b, 733 d, references). Through the same law of adaptation, also, the solids are brought into such relationship with each other by the reciprocal influences of disease as it may affect various parts, and whatever the variety in the coexisting conditions, that a single remedy, as bloodletting, a cathartic, an emetic, &c., may be universally suited to the several pathological states. These cases are perpetually before us; and were not my philosophy true, all our efficient remedies would forever aggravate some part of a compound disease. The principle is the same in both the cases, and our experimental knowledge of its truth in the latter confirms what I have stated as to the blood in the former (§ 143, c).

847. h. Were not the foregoing all-wise provisions established in

the constitution of animals, all the diseases which it may now throw off would require for their removal the interposition of Supernatural Power (§ 133 c, 151, 152). The morbific blood would not develop disease in one part alone, as overlooked by the humoralists, but throughout the universal organism; and the blood itself, becoming progressively diseased in the ratio of its mcrbific influence upon the solids, would hasten the general catastrophe in an increasing ratio. The blood of the victim of small-pox would poison more and more profoundly, while the purulent matter would erode the body and lend its powerful aid in the universal work of destruction. Nature, however, comes out triumphantly, and in an allotted time. We must look to the philosophy which I have taught for the only possible interpretation; while it opens a door to a stupendous, harmonious system of fundamental laws (§ $233\frac{3}{4}$, $500 \ k$, m, 841, $893 \ a$, n, $904 \ bb$, 905).

848. It will now be apparent from what has been said in the preceding section, how it is that remedial agents will call into salutary reflex nervous actions various parts of the body not affected by disease, but whose susceptibilities are increased by morbific reflex nervous actions excited by absolute desease, and upon which parts the remedial agents might otherwise be inoperative. In this way, therefore, various parts may be rendered instrumental in establishing those influences upon the seat of disease which enables Nature to take on the recuperative process (§ 137 d, c, 143 c, 149-151, 152 b, 163, 514 h, 674 d). Whatever, too, may be the complexities of disease, the right remedy will be at least compatible with the whole condition

(§ 870 aa, 891 g, 891 $\frac{1}{2}$ e, f, 892 c, d, 892 $\frac{1}{4}$ c, d).

849. Upon the foregoing fundamental ground (§ 847), it appears, a fortiori, that if perfectly healthy human blood be allowed to flow into the veins of a subject affected with fever, or scurvy, or inflammation of any important organ, in quantities sufficient to produce an effect, while, also, a corresponding quantity of morbid blood flows out of the veins, such healthy blood would aggravate the disease (§ 136, 137 b, c, e, 149, 152). This induction from principles has been practically demonstrated, even to the death of human subjects, although the quantity of healthy blood transmitted was small. There was no natural relation between the healthy blood and the diseased solids, and the former, therefore, became morbific (§ 152, b).

850. It follows, also, from the foregoing physiological principles, that morbid blood may excite disease in a healthy subject, if transferred in certain quantities into the circulation. It may be necessary, however, that the quantity should be large; when, as soon as morbid action follows, the whole mass of blood will become affected, and thus brought into harmonious relation with the diseased state of the solids (§ 847, e-g). Hence, the great mass of blood is altered from its natural state by the solids, and convalescence may, therefore, begin spon-

taneously, or through the intervention of art.

It is scarcely necessary to add, that the present case is entirely different from those in which it is assumed by the humoralists that the whole mass of blood is primarily morbific. The injected portion is like any other morbific agent circulating with the blood; nor does it assimilate to itself, any more than wine, or bile, when so injected, the circulating mass. The general mass remains under the control of the solids, and receives from them its deterioration should disease ensue.

Nor doss it follow that the injected blood will produce the same condition of disease as that by which it was altered (§ 350, nos. 44, 45, 97, 744, 810), or be fatal either in this or the other case (§ 849).

851, a. Finally, the humoral pathology chains the mind in ignorance, and whether with the learned man, or the bolder empyric, leads equally, in its application, to the most unhappy practical errors. violent assumption is equally made by either, that the blood must be purified or otherwise changed by the direct action of remedial agents; that its impurities must be purged away; that the means are taken into the circulation, even calomel, blue pill, and other less soluble substances; that they are then conveyed into the torrent of the circulation, cleanse, neutralize, purify the blood, and reinstate its natural condition, as necessary to the subsidence of disease in the solids. is all the work of the blood-making faculty of calomel, opium, and nux The treatment, therefore, is apt to be governed by this in-

dication (§ 1087).

Or, does the humoralist resort to bloodletting; he professes to carry off the poison, the "peccant humors," &c., by abstracting some dozen ounces of blood from the circulating mass. But this is neither conformable with fact, nor with the hypothesis; since the great bulk of the poison remains behind, and since, also, at the beginning of the disease, the infected mass must be greatly less morbific than when remedies are applied at its advanced stages. The humoralist affirms, indeed, that an inappreciable quantity of miasma, or of the virus of the dissection wound, &c., enters the circulation and throws the whole mass into a ferment, and that this goes on progressively increasing; nay, that one drop of blood thus affected is sufficient to contaminate the whole mass, "as a little leaven leaveneth the whole lump," or "as one spoiled herring will taint the whole cask" (§ 350, nos. 44, 45, \$21 c). And yet may a severe grade of disease be suddenly overcome by a single bloodletting, or by a cathartic, or by an emetic, or by a full dose of quinine (§ 284, 330, 892 b, 900, 902, 905 a, 970 c).

But the humoralist, learned or unlearned, is little prone to abstractions of blood in recent times, and now, more than ever, proceeds upon the broad basis of his pathology. Cathartics are his special favorites, for they purge off the humors, and cleanse the blood; or if it be quinia for an intermittent, it is administered with a view to neu-To him the vis medicatrix Naturæ is like the midtralize a poison.

night darkness to a blind man (§ 240, 839, 853).

851, b. How different the practice of the solidist; how enlarged his philosophy; how various his remedies; how consistent his doctrines; how important to humanity! Let a single example illustrate and confirm his theories. According to the nature of the predisposing causes, and the exact pathological conditions, he cures ophthalmia by an emetic, or cathartic, or by bark, or arsenic, or iodine, or mercury, or bloodletting, or leeches, or blisters, or electricity, or local sedatives or stimulants, and by light or darkness (§ 675, 686, 904 a).

851, c. I regret the necessity of the parallel and the contrast. But I speak of facts and philosophy; nor should I be true to my duty did I not speak with honesty and frankness. If wrong, refutation will be

easy and gladly accepted (§ 1 a).

THERAPEUTICS.

852, a. Therapeutics is the great ultimate object of all medical inquiries. It refers back to the natural physiological states of the body, and to the laws which govern organic beings in their healthy condition. It takes in the whole range of pathology, since there could be no rational treatment of disease without a previous investigation of its causes and nature, and a proper knowledge of their relative laws and principles. Having, also, for its specific objects the means of cure, and their just application to disease, therapeutics comprehends all the vital relations of the Materia Medica.

Notwithstanding, however, the vast range of principles which it embraces, and the immensity and complexity of its details, it has, essentially, but one fundamental object; namely, that of inducing such changes in the morbid organic properties and functions as will enable

them to return spontaneously to their natural state (§ 177).

852, b. We thus find that all parts of our inquiry are intimately bound together; that together they form a perfectly consistent whole; and that as a whole each part is necessary to all the rest (§ $137 \ a$, $639 \ a$).

Wonderful, indeed, that so vast a subject should be so simple in its elementary principle; but more wonderful still that a principle so simple should be more complex in its attributes than all other princi-

ples in nature (§ 133-153, 177-182, 222-233).

853. It is an attribute of the properties of the Vital Principle that they possess an inherent tendency to return from their morbid to their natural states. This endowment has given rise to Therapeutics, and is indispensable to the perpetuation of organic beings. It belongs, therefore, to plants as well as to animals (§ 133 c, 185). The object of art, in the treatment of disease, is to place those properties in a condition which will enable them most readily to obey this natural tendency (§ 189). This is what I mean by Nature, and the vis medicatrix.

854, a. Remedial agents operate upon the same principle as the remote causes of disease (§ 150-152). They can never transmute the morbid into healthy conditions. That is alone the work of Nature (§ 524, d, 862). Art can only make the best use of her laws (§ 237).

854, b. The most violent poisons are among our best remedies. "Ubi virus, ibi virtus." In a medical sense, however, we do not know them as poisons, but as among the choicest blessings bestowed upon man. Poisons, however, they may all become when not employed in their proper relations to disease (§ 150, 673, 674). That it may be properly known in what respects they are remedial, they should be studied in their morbific aspects; studied in their morbific effects upon diseased, not upon healthy, conditions (§ 137, d, &c.). Thus, also, shall we employ them with a more solemn reference to their morbific capabilities, and under the deep conviction that when injudiciously administered they cannot fail to exasperate disease.

854, bb. The foregoing consideration demonstrates an important fallacy at the very foundation of homœopathy. It affects very seriously its main principle as founded upon experiments with remedial

agents upon the healthy subject. But the fact that this objection has not been advanced is an evidence of the little consideration which is bestowed upon the vast differences between the operation of remedies upon healthy and diseased organs; and if such palpable distinctions be not observed, what must be the amount of knowledge in respect to the immense variety in the degrees and kinds of susceptibility in different forms of disease and in the variable pathological states of a common form (§ 137 d, 150, 191, &c., $892\frac{1}{4}$ b, 855, 856)? There is nothing, however, more important in medicine than the principle which I am now considering. But, there can be little hope of its general recognition till experiments upon animals with a view to elicit the causes and the philosophy of disease as manifested in the human race shall have been abandoned. Not till all indications as to the curative virtues of remedial agents shall become limited to observations upon man alone, and man in a state of disease. Not till all others shall have ceased. Not till principles in medicine are wrested from the hands of the chemical and mechanical philosophers (§ 676, b). Not till a proper decision can be obtained between the two methods of considering disease as propounded in sections $5\frac{1}{2}$ a, 675, 686 b. Should the last of these references prevail, then must fall, as an indispensable prerequisite, all the principles and suggestions which have been derived from the philosophy which concerns the external world, and yield to that system which I have set forth as the foundation of the method of interrogating disease according to that section to which this special reference is made (§ 686, b, 1058 b, note, 1059).

854, c. In respect to the absolute influences of all remedial agents of positive virtues, they are essentially morbific in their remedial action; as will have been duly explained (§ 893, 902). They are alterative in disease, as in health, in respect to the vital properties and actions. There is no difference in principle as to their absolute action. In certain remedial quantities many may induce, in the healthy organism, various degrees of disease with as much certainty as those agents which are called morbific. It is upon this alterative nature of remedial agents that I have founded, in part, my Therapeutical Arrangement of the Materia Medica (§ 893, 897-901, 1059).

854, d. The difference, in effects, between the truly morbific and remedial agents is two-fold. Morbific causes make their deleterious impression, in a general sense, more profoundly and more permanently. Positive remedial agents, in certain quantities, exert such morbid changes as are not profound, and from which the properties of life may recover, by their inherent tendency, their normal state. But, there is also another difference which is fundamental. The two classes of agents not only affect the vital states in different modes, according to the special virtues of each, but each establishes changes according to the existing condition of the vital states (§ 137 d, 149, 150, 854 bb). The Materia Medica is necessarily founded upon the foregoing principles, however it may have been hitherto unexplained, or however it may not be now admitted (§ 2 b, 143c, 895, 902 f).

854, e. In the treatment of disease, therefore, we do but substitute one morbid action for another. Physiological processes do the rest.

854, f. In consequence of the laws of organization, the approximations of morbid conditions are such as to enable us to establish upon a certain combination of phenomena certain general principles of

treatment, corresponding harmoniously with the principles through which the morbific agents have induced the adverse changes. The curative principles, therefore, will be liable, in all cases which are not exactly alike, to certain modifications according to the modifications of disease; and these are to be learned, especially, from the vital manifestations (§ 150–152, 177–179, 182 b, 638, 650, 670, 672, 676,

677, 680, 733 e-i, 741 b, 745, 756 b, 758, 766, 854 bb).

855. Many of the remedies for disease, especially when Nature is engaged in the recuperative process, consist of the ordinary means of maintaining health, such as the various modes of exercise, change of climate, &c. These means now operate with greater power than under circumstances of health, and must therefore be carefully adapted to the existing state of the patient, since, when unduly applied, they aggravate or reproduce disease like agents of absolute virtues (§ 137 b, 143, 147, 149, 150, 854 bb, 872 a, 902 m). When productive of useful effects they co-operate in a direct manner with the tendency to restoration which had already begun (§ 672, 733 e-i).

Of the same nature, also, are the agreeable excitements of imagination, of society, of rural scenery, of joy, hope, amulets, charms, &c. While, also, some of these means may be powerfully morbific they may be equally curative of disease (§ 226, 227, &c., 844, 1067).

856, a. There are yet other remedial means which may be called negative, or such as merely allow Nature the fullest opportunity to go on with her recuperative efforts. They make no impression upon the vital conditions; and all the changes to which they administer grow exclusively out of the constitutional tendency of the properties and actions of life to return to a state of health; which is the import I give to the convenient term Nature when employed therapeutically.

856, b. Now the means of cure embraced in this and the preceding sections are of the highest moment in every case of disease; and yet are they the most neglected except by those who depend on Nature alone (§ 854, bb). In a large proportion of chronic forms of disease, and where they are acute but not profound, little else is needed than a modified system of hygiene adapted to the individual cases. Coming to graver modes of disease, and where active remedial agents are required, the negative means are more important than in the former cases, and nothing more so than a rigorously low diet.

Here, then, is opened a wide door for the contemplative and practical inquirer. Here recuperative nature is displayed according to the Ordination of Providence throughout brute creation. The animal sickens, "starves," and thus nature works the cure. Man alone vio-

lates her law (§ 239, 240).

857. It has been seen that morbific and remedial agents, even the natural agents of life, acting with certain intensities, and under given circumstances, may be entirely on a par; each leading with certainty to morbid changes which may transcend the restorative disposition of

the organic functions.

This fact involves a principle which is fundamental in the Materia Medica; that of limiting the quantity of remedial agents, and the duration through which they operate, so that they shall only establish such changes in the vital conditions as will enable them to exert their fullest tendency to return to a state of health. Beyond that point positive remedies determine morbid changes that are embarrassing to

Nature, and may be far more so than the conditions which had been instituted by the primary cause of disease. This is a matter of constant demonstration; and if we connect with it the more general abuse of food, their common mode of action becomes so obvious, that he who may pause in his excessive medication should take the hint and unite

the advantages of the negative treatment (§ 856).

I am now upon ground of the first importance in practical medicine. I have endeavored to enforce and to illustrate that importance by calling up, in a variety of shapes, those fundamental physiological laws which give the greatest determination to the effects of remedial agents, in respect to their amount, and the frequency of their repetition (§ 889, l). I leave out of consideration, for the moment, the vast questions which relate to the right adaptation of remedies as concerns their nature, and the order of their application (§ 150). I would dwell abstractedly upon the dose and the frequency of its repetition. Too little reference to the natural constitution of the properties of life and the laws which they obey in their natural states, and too little dependence upon recuperative nature—ay, I may safely affirm, too general an abandonment of that foundation, and even a universal ignorance of the practical bearings of some of its most important elements (§ 516 d, no. 6, 524 d), have mainly led to an abuse of remedies in respect to doses and their repetition which has been more pernicious than errors in their appropriate nature, and their order of application. That abuse, indeed, in connection with the stimulant and feeding practice, is the whole secret of the origin of homoeopathy, and of its extensive prevalence (§ 621, a, 1068).

It must be conceded, however, that there is no attainment in medicine so difficult as that which relates to quantity or dose, or which requires so much critical observation of disease; and next to that is the time when the dose should be repeated, or varied, or some substitute made. The most delicate points are relative to dose and repetition, and these can never be attained with any accuracy without a full appreciation of certain physiological laws which I have endeavored to expound as far as my own apprehension of their nature will admit (§ $5\frac{1}{2}$ a, 516 d, no. 6, &c., 686). It should be kept steadily in view that all efficient remedies are morbific in excessive doses, that what would be perfectly inert in one condition of the same disease may be fatal in another modification, and that the impressions produced are continued beyond the time of their direct operation, according to the nature of the remedy, its dose, the precise pathological conditions, &c. (§ 149, 150, 163, 191, 514 g, 516 c, 516 d, no. 6, 550, 552, 556 b, 558 a, 673). A repetition of the means before the influences already established shall have ceased, or have duly lessened, or have fallen short of the intended amount, either prolongs the cure, or exasperates and

multiplies disease (§ 872).

858. The foregoing principle is strikingly shown, and a large reliance upon Nature as strongly enforced, by the impracticability of art in arresting the progress of the self-limited diseases, and by their spontaneous termination in health. We cannot, by any active treatment of small-pox, &c., place the morbid properties and functions in a more advantageous state to exert their recuperative principle than had been already done by the very causes of the disease. On the contrary, all active treatment embarrasses Nature, and is generally mor-

bific. Accidental conditions, such as inflammation of important organs, may spring up in the truly self-limited diseases, which may require a decisive impression from remedial agents; and it is an admirable law of nature that, in proportion as these special exigencies may arise, the influences of their pathological conditions will enable the more general affection to bear the treatment that may be demanded by the contingent derangements (§ 150, 156 b). But we must be careful to avoid such agents as may interfere with the established tendency of the general affection to subside spontaneously (§ 847 g).

Nowhere, however, is the recuperative tendency of nature, the vis medicatrix natura, so forcibly displayed as in the brute creation, where instinct alone obtains, and where organic life moves on unshackled by artificial habits (§ 856, b). All is the work of physiological processes.

859, a. We see, therefore, more and more, that, in therapeutics, we should cautiously avoid those fallacious inductions which have been drawn from the action of remedial agents upon man in health, and even upon animals and plants, and which constitute a part of the "experimental philosophy" of the age (§ 854). It is, however, one of the worst corruptions that has crept into medicine. I have variously indicated its want of philosophy, and the evils of its practical application. They are summarily comprehended in principles set forth in sections 149–152. These principles I regard as among the foremost in therapeutics; and here, but for other reasons, they would have been first announced.

859, b. To arrive at any just knowledge of the physiological relations of any remedy to a given form of disease, it must be considered in the opportuneness of its application, its appropriate degrees, and according to the varieties of constitution, age, habits, sex, &c., and according, also, to the nature of the affected organ, to the variations of any given disease, its reflex nervous influences, and as those influences may be modified by the remedy, and the connection of the particular remedy with other agents that may precede, or follow, or be simultaneously employed, and all other circumstances that may favor or embarrass its most salutary effects (§ 133–163, 535, &c., 574, &c., 585, &c., 622, 650, 651, 659–662, 671–673, 675, 685, 686, &c.).

859, c. Nevertheless, the salutary action of remedies, or rather the aid which they may contribute to the recuperative process, is commonly in the ratio of the intensity of disease. This grows out of the constitutional nature of the organic properties, as already variously considered, and *Medicine* simply administers their laws (§ 235, 237).

860. All remedial agents of positive virtues, like all morbific ones. alter the properties and actions of life, cateris paribus, according to the nature of each agent (§ 652). Each one affects them in kind, and in a way more or less peculiar to itself. Hence, mainly, the varieties in any common genus of disease, as in inflammation and fever; hence, also, the modifications of a common mode of treatment, and hence the importance of selecting the cathartic, the emetic, &c., whose virtues may be most appropriate to the precise pathological condition of the case before us, and introduce the right pathological change.

861. There are but a few diseases which have a determinate tendency to a state of health, and these are, in consequence, denominated self-limited. Sooner or later, however, there is apt to arise in a large proportion of diseases a spontaneous subsidence This may not be

true of a great proportion of cases; but the restorative disposition is often manifested in a great number of instances of any given disease, while a greater number of the same disease may run on to a fatal termination. Their morbific causes are not such, as in small-pox, &c., as to establish modifications of the vital states which go on through regular changes till they terminate in health (§ 858); though there may be a strong tendency of this nature existing, as seen in intermittent fevers. New agents (called remedial, but in reality morbific (§ 901)) may, therefore, be made to operate so as to develop the restorative principle where it might otherwise fail, or introduce it sooner than it would occur spontaneously; and thus place the disease on a par with the self-limited, whose predisposing causes surpass all remedies, in a fundamental sense, in developing a tendency to the restorative process.

It is also important to consider that the restorative process, in a general sense, is most readily established near the invasion of disease,

whatever its violence (§ 557 a, 868, 869, &c.).

862. Nature resorts to a variety of expedients in carrying out her process of cure. The principle is the same in all the cases, and its details illustrate what has been hitherto so obscurely meant by the vis medicatrix. It is the same, through all the intermediate conditions and complications, from those diseases which are marked by a definite order of results, as in the self-limited, to the most intractable maladies. A clear and impressive example of the nature of the principle is seen in the progress of an abscess toward the surface, to its termination in health (§ 733). Whenever inflammation passes its formative stage, there is always some sensible demonstration of the modus operandi of the vis medicatrix. These visible results are of a depletory nature, like redundancies of bile, and consist of lymph, serum, pus, &c.; and, although the results of salutary changes in the morbid states, and conducive to the farther subsidence of disease, they are apt to constitute as great or greater evils than the disease whose decline had led to their formation (§ 732 d, 733 a). It is the business of art to prevent these intangible consequences, although they grow out of a law by which Nature aims at preservation and cure (§ 733, e).

863, a. In the treatment of disease we endeavor to imitate Nature in her spontaneous efforts at relief, so far as principle is concerned. If these efforts result in the formation of new products, or an increase of the natural ones, in certain modes of disease, our remedies should be such, in the same, or analogous affections, as will be likely to determine an increase of the natural secretions (§ 732 a, b, 756 b, 785, 801, 805). And, although these effusions do not relate directly to the parts that may be mainly diseased (as is generally, though not always, true of Nature), they are significant that favorable impressions are made upon these parts. In the natural cure, also, it is these vital changes, far more than the physical products to which they give rise, that determine the cure. This is artificially exemplified in the influence of vesicants, rubefacients, issues, moxa, &c., upon deep-seated inflammations, and proving my doctrine of reflex nervous action.

863, b. Nevertheless, these redundant products, whether of Nature or of art, contribute more or less, as means of depletion, to the restorative process. The part, however, which they perform will depend upon a variety of circumstances, upon the nature and seat of the

disease, upon the means employed by art, upon the organ from which the effusion takes place, and whether from that which is diseased or from another which may only sustain a moderate sympathetic derangement, upon the nature of the product, and whether it be the conse-

quence of disease or induced artificially.

863, c. If Nature institute the effusion, it is commonly far more curative than when flowing from remedial agents. The latter operate mostly by changing the morbid states; and although they are designed to imitate nature in their general results, they may be yet intended to prevent many of the consequences of spontaneous cure, such as effusions of lymph, serum, and blood, and the formation of pus. But, in accomplishing this, they institute an increase of those natural prod-

ucts which issue upon open surfaces (§ 862).

863, d. The increased product is most curative when it proceeds directly from the affected organ. This is true both of Nature and of art. If produced artificially from other organs, the curative effect will be generally the greatest in proportion to the importance of the organ; and will so far depend upon reflex nervous actions set up by the vital changes which give rise to the increased product; as when cathartics augment the bile, the intestinal mucus, &c., or antimonials the perspirable matter. Hence, it will be seen that the vital changes induced will depend, in any given form of disease, upon the nature of the cathartic by which the bile or intestinal mucus is augmented. Calomel, or jalap, or castor oil, &c., may be speedily curative, when aloes, or elaterium, or croton oil, &c., may be as speedily fatal. So, again, as to "sudorifics," as they are called. Antimonials or ipecacuanha, for example, though they but soften the skin, may overthrow the most profound inflammations, when hot water, or herb teas, would be perfectly inefficient, though they bathe the skin in perspiration. "Sialogogues" fall under the same philosophy. Horseradish is one of them; but though its mastication may keep up a flow of saliva, it will only aggravate an inflammation which mercury, without salivation, may soon subdue. We come thus to understand how all remedial and morbific agents affect the vital states in conformity with the exact virtues of each agent and the existing condition of parts upon which their effects may be exerted (§ 150). We are thus enabled to understand why the vomiting which is produced by an offensive odor, or by tickling the fauces, or by disgusting objects, or any other mental emotion, or by warm water, is less effective in breaking up disease than when produced by an infusion of mustard seed; and less from the last than from the sulphate of zinc, and less from this than from ipecacuanha, and often, perhaps, still less from ipecacuanha than from tartarized antimony, and perhaps often still less from either than from ipecacuanha and tartarized antimony combined. One agent impresses the organic properties of the stomach more profoundly and in a different way from another, and therefore excites and modifies the nervous power in a way peculiar to itself, which, when reflected upon the diseased parts, will affect their condition in modes corresponding with the peculiar impression that had been made by the nauseating influence exerted on the mucous tissue of the stomach (§ 226, &c.). And so of every other remedial agent which produces its effects upon remote parts by primary impressions upon the gastro-intestinal mucous membrane, or the skin, or any other organ. The same is also equally true of mor-

bific agents (§ 650, 653). And here, through the foregoing philosophy, we may understand the reason for the differences in results between the action of cathartics and the analogous effects of emetics upon the intestine. We may regard it, for example, as manifested by tartarized antimony in the double aspect of a curative and morbific agent as it may happen to prove emetic or cathartic. If it fail of the former effect, it will, nevertheless, have produced more or less of that profound impression upon the stomach which is peculiar to its own virtues in their relation to the gastric mucous tissue, and when it passes on to the intestine it exerts not only a more depressing effect upon the whole organism, but may act upon the intestine as a profoundly morbific cause, and develop reflex nervous influences that light up inflammation in the lungs, or extinguish life, as is often the case, ere its purgative effect has ceased (§ 150, 226, 228). The fundamental principles are the same throughout, and rest mainly on reflex action of the nervous system. No chemical, physical, or humoral hypothesis can withstand its force, for a single moment, with the enlightened practitioner. In a practical sense, it should be the perpetual study of physicians; the touch-stone, as it were, by which all remedies are selected (§ 149–154, 222–233 $\frac{4}{5}$, 475 $\frac{1}{2}$, 500 k-nn, 514 f, 647 $\frac{1}{2}$, 891 $\frac{1}{2}$ k, 893 a, c).

A great variety of other practical conclusions follow in the train of the foregoing principles. We see, for example, from what is known of the rapidity with which emetics produce vomiting, and the reaction which speedily follows, that they exert their alterative effects upon diseased parts with great suddenness, and that the influence of mercly nauseating doses of the same agents may be exerted more gradually, and may therefore, according to the nature of their virtues, be more profoundly alterative. The depressing nausea which precedes the emetic effect of tartarized antimony may be remarkably productive of an alterative influence upon all the organs of the body (§ 514, h-m); prostrating the circulation, and, when prolonged, removing croup, or pneumonia, more effectually, perhaps, than by the speedy operation of an emetic. Hence, also, it is obvious that emetics are mostly useful, in their therapeutical aspect, soon after the invasion of disease, when unembarrassed by the force of vital habit (§ 535, &c.), or during the intermissions of fever when nature is inclined to the restorative process, and when, as in either case, she may require only a sudden and temporary shock to place her permanently in the right way.* The philosophy of their success in these cases appears to be perfectly simple. The morbid change, in one case, having but just begun, and Nature, in the other, being inclined to restoration, reflex nervous influences which radiate from the stomach during the action of an emetic easily establish new changes in the diseased conditions, when the properties of life are enabled to obey, at once, their natural tendency to return to a state of health. This simple principle, therefore, leads us to understand that the most auspicious time for administering an emetic in intermittent fever is when the stage of intermission is fully formed. There is now the greatest suspension of morbid action, and the organic states are going the right way. We critically seize this moment to prevent Nature passing again into a state of incubation; or, perhaps, a better time is not long before the expected access of a paroxysm, since the artificial change being made about the time of the access, the predisposition is so crippled at this particula. * See p. 298, 4 4761 h.

juncture that the artificial change breaks up, most effectually, the succession. This interruption of the access of a paroxysm destroys the paroxysmal habit, and the disease is at an end.* The same philosophy is here concerned as that which respects the influences of bloodletting just before the access of the cold stage, and goes to illustrate the modus operandi of that remedy (§ 986, &c.). But the most advantageous time for bleeding, if not demanded by some inflammation, or by high arterial action during the rise of the hot stage, is soon after that stage begins to subside; and this, next to the time just antecedently to the expected access of the cold stage, is the best period for administering an emetic; and this, also, is the best period for the exhibition of a cathartic, unless given along with the emetic before the access of the cold stage. The same philosophy applies whether Nature be engaged in a restorative movement or be about to enter upon a state of incubation. The expediency as to time depends upon the kind of remedy. In either case Nature may be readily turned into her favorite course. Conditions are instituted which correspond with those through which the morbid properties take on spontaneously the progressive changes that result in health; as shown by the coincidence in the immediate results of the remedies, and those which ensue at more distant times when no remedies have been applied. In either case, whether the artificial or the natural, sweating breaks forth, the secretions of the liver, of the intestinal mucous tissue, of the kidneys, &c., are poured out. By anticipating nature we aid her in consummating her efforts at relief; while the artificial change so far transcends the spontaneous improvement that Nature is greatly started along in her recuperative process, and often obtains an impulse by which she passes on triumphantly through an uninterrupted series of salutary changes till the properties and actions of life become restored to their natural state (§ 672, 675).* And here we may look at one of the reasons why cathartics are more remedial than emetics after disease becomes established; for, although very profound reflex nervous actions may be determined by emetics through the mucous tissue of the stomach, the impression upon that organ, as exerted by the most curative, is much more transient than that upon the intestine by the best of the cathartics (§ 514 g, 516 d, no. 6). This, however, is only a principal one among other reasons, of which the difference in virtue is the greatest. Hence, an important corollary, that the therapeutical effects of cathartics and emetics, and, indeed, of all other remedies, will depend, other things being equal, upon the particular virtues of the agent, and the time, within certain limits, during which it may act upon the gastro-intestinal mucous tissue (§ 516 d, no. 6).

We may remark, also, as intimately related to the principles and practice now under consideration, and as farther illustrative of the importance of adapting our remedies to the precise pathological condition of any given form of disease (§ 675,870 aa), that cathartics, unless united with an emetic, are apt to be detrimental if exhibited just before the access of a paroxysm of intermittent fever, and to bring on the attack. But this is less the case with an appropriate cathartic, such as calomel and jalap, if associated with an emetic; since the operation of the cathartic is then more immediate, less prolonged, and its general irritation more or less counteracted by the prostrating effect of the emetic It is the same principle which is concerned wher

^{*} See Notes K L pp. 1119, 1120.

antecedent loss of blood lessens the constitutional irritation of cathartics, or when the prostrating effect of an emetic prevents the abstraction of blood, however apparently different in the two cases. The principle reaches very far into the philosophy of medicine, and concerns, especially, the order in which remedies should be applied. As one of its more obscure details, I may say that the union of opium with a cathartic, for the purpose of moderating the irritation of the latter, is exactly equivalent to either of the immediately preceding examples.

From what has been just said, we readily see one of the principal distinctions between cathartics and emetics. The non-stimulant emetics reflect a nervous influence which depresses the circulation throughout their widest range but excites perspiration as a consequence of salutary changes, while, on the contrary, cathartics are more or less apt to stimulate and excite the circulation at first, and do not often affect, in a sensible manner, the functions of the skin. A knowledge of these differences, as well as of the analogies which prevail among the influences and results of different remedies, and also of their modus operandi, is indispensable to a successful application of those suggestions which are afforded by Nature in her unaided efforts at

restoration.—Note Ee p. 1133.

863, e. In respect to the curative influence of increased effusions, much will depend upon the intrinsic nature of the product which artificial or natural changes may bring about (b). By the natural process, in local inflammations, lymph, and serum, and pus are a good deal alike in the amount of effect (§ 732, d), and redundancies of bile are next in the relief of hepatic derangements. Least of all, in respect to organic products, is increased mucus. But this will depend much upon the nature of the part. It is most curative in inflammations of the lungs, far less in intestinal inflammation, and still less so in inflammation of the bladder (§ 133, &c.). The inorganic products contribute very little, by their augmentation, to the curative process, whether naturally or artificially induced. Perspiration is more so than urine. When these products, however, flow abundantly, the salutary effects depend mostly upon the vital changes from which the redundancies emanate. Humoralism, on the other hand, imputes all to the augmented product (§ 514, h). That is the difference between solidism and philosophical humoralism. The former detects the cause and renders it his polar star in his philosophical and practical movements; the latter mistakes the effect for the cause, analyzes the blood, or the saliva, or the urine, and according to the real, or artificial, or imaginary developments of the test glass and crucible, he neutralizes an acid or an alkali, purges off ozmazome, or picromel, or cholesterine, and taps the abdomen to cure the dropsy; while the charlatan "holds up the mirror," and all the world believes the shadow reflected "Nature" (§ 5½, 349 d, 851).

863, f. But Nature has one means of depletion which stands for all the rest. And so it does in the hands of art. This, I need not add, is loss of blood. Here Nature and art meet upon common ground. Both interpose the remedy for the direct subversion of disease, and both equally prevent thereby the formation of other products (§ 805, 890 d-g, 1019). Indeed, such is the magnitude of this remedy, and such its direct effect in changing pathological conditions, that I shall enter largely upon the philosophy of its operation, and its applicability to disease.—Notes F p. 1114, Fr p. 1135, Ge p. 1138, It, p. 1139.

863, g. What we have now seen of Nature and of art, in respect to inflammatory diseases, is equally true of fever. The effusions, however, which Nature institutes in fever are less various than in inflammation, and proceed from organs connected with the external world. But here they are more universal, and it is here as fever is complicated with venous congestions that Nature makes the same demonstration with the remedium principale as she does in obstinate affections of the lungs, or the stomach (§ 805).

863, h. It is a common event for disease to persist until great emaciation, and other signs, denote approaching death, but, notwithstanding, for the restorative process to set in, and where no secreted products had apparently contributed to the change. In these cases, however, the emaciation has been more or less an equivalent. And here, again, a lesson may be taken from Nature, on the subject of diet, by those who will not listen to her law as proclaimed by the instinct of animals. But even where disease is maintained by errors in food, there

may be yet remaining hope from emaciation (§ 1007 h).

864. It appears, therefore, that the salutary changes which occur spontaneously in all inflammatory and febrile affections lead to a variety of evacuations from the secretory and excretory apparatus, and within the organization, of which effusions of blood are the most efficient. Art, in its imitation of Nature, has proved that she is the only guide; and since fever and inflammation comprise all the severe forms of disease, and as there is nothing in the results of spontaneous changes which correspond with those induced by tonics and stimulants, we may safely conclude that those practitioners who often resort to that class of agents have but very imperfect views in physiology and pathology, and are astray from the path of Nature.—Note Ee p. 1133.

865. No remedial agents are truly specifics; though, for conventional purposes, the designation is useful. Mercurials will often fail of curing syphilis, where a non-stimulant diet may succeed alone. Cinchona may exasperate an intermittent, when arsenic or cobweb would readily succeed. There is no remedy, indeed, however adapted to the cure of any given disease, which will not sometimes fail, and admit of a substitute apparently quite different. Bloodletting, cathartics, &c., will generally remove intermittent inflammation; but cases occur in which the special febrifuge virtue of cinchona is necessary.

866. All remedies, therefore, are only so in relation to diseases upon which they may exert salutary effects (§ 149, 150). Cinchona, for example, is a remedy for intermittent fever if no local diseases of severity exist; but if so, it will commonly exasperate the fever, and is then a morbific agent (§ 854, 857). Its tonic virtues then transcend its febrifuge, of the first of which arsenic and cobweb are destitute.

The former of this remarkable combination of virtues may be the best for enfeebled states of the system, or of the stomach, if no inflammation be present; otherwise, it is morbific. It should be constantly before us, that a tonic, an antiphlogistic, &c., are only such when appropriate to the case before us. With this understanding, we are led to investigate the exact pathology of the case, and its various attending circumstances (§ 673, 675, 685, 686).

867. The curative effect of remedies is more or less progressive. When the primary state begins to give way, a new pathological condition is introduced, and so on in regular progress where there is an

uninterrupted decline of disease (§ 672). But it rarely happens that diseases are diverted from the essential pathological character with

which they begin.

The curative effect commences at the first moment a favorable impression is made upon the seat of disease or upon any part capable of participating sympathetically in the restorative process, and terminates when that exact change is made in the diseased properties and functions which is most conducive to their spontaneous recovery. When remedies are carried beyond that point, they are apt to become morbific. Hence it is one of the most important, but difficult acquisitions, to determine when our remedies should be discontinued, or moderated.

868, a. It should be a great object of art to render the associated train of pathological states as short, and make it consist of as few changes, as possible. In a general sense, therefore, where disease is intense, the first remedial impressions should be strongly made; but, in doing this, the right agents should be selected. It would answer, for instance, to exhibit a decisive dose of calomel and jalap, at the onset of pneumonia; but it would be sad practice in inflammation of the intestine. Bloodletting, however, is adapted to either case, and is the right initiatory remedy for both.

As the favorable changes advance, our remedies should become milder and milder, till that critical point is attained where Nature requires only the occasional interposition of art to accomplish the removal of some slight obstacles that are more or less liable to spring up during convalescence; such as constipation, deficient secretion of

bile, &c.

868, b. Our remedies may be perfectly right, and yet disease shall increase by the force of its intensity (§ 685, no. 9). In such a case, however, we may have fallen short of the due amount of the remedial agent; and this we shall see to be often true of bloodletting. But it is rarely so of any internal agent; there being a prevailing disposition to medicate largely. We have thus a positive abuse of drugs and a negative abuse of bloodletting. Being sure of the right, we should steadily pursue it; repeating the remedy, or associating, or substituting, others of analogous virtues in relation to the case before us, till their effects are pronounced by a manifest decline of the symptoms.

869. The rapidity with which the full salutary changes will be effected will depend upon a variety of circumstances; but mainly upon the period of the disease. All diseases being most easily and speedily arrested near the time of their beginning (§ 557, a), the difficulties increase in proportion to their unmitigated duration, or any increase they may sustain. They soon begin to acquire the obstinacy of a morbid habit (§ 535, &c.), to involve sympathetically other organs, and to result in disorganization, effusions of serum, &c. (§ 660, 712-718,

732 d).

870, a. Some remedies, in their greatest proper latitude, make a decisive impression much sooner and more effectually than others, under the same circumstances of disease, and where either may be appropriate. Bloodletting, in inflammations and fevers, operates far more immediately and decisively than any other remedy, and cathartics are generally next. And so of many individual cathartics which may be appropriate to a given condition of disease. The saline may be slowly and moderately useful, and some of them better than oth-

ers; castor oil more speedy and effectual; jalap more so; calomel far more so; and the united force of calomel and jalap may greatly transcend either. Sometimes, however, as we have seen, a fever at its onset may be completely subdued by the alterative action of an appropriate emetic. Tartarized antimony will do it with the greatest certainty; ipecacuanha comes next; but most of the other emetics would be perfectly useless or detrimental. The union, however, of antimony and ipecacuanha improves the useful alterative virtue of each, and lessens the chance of morbific action from the antimonial (§ 150).

870, aa. Remedies sometimes operate with great and rapid effect upon one part of a compound disease, but may fail in respect to other parts; or, if not justly applied, they may assuage a part of the disease, but, from their want of proper relation to other parts, they may prove morbific to these conditions, and thus indirectly reproduce that part of the malady which they had been instrumental in subduing. But this will not happen with the right remedy (§ 150, 552 b, 665, 848). Bloodletting, for example, may quickly subvert pneumonia when complicated with small-pox, but will not shorten the natural progress of the more general malady (§ 858). But the remedy will now be perfectly compatible with the whole condition of disease; since the local inflammation has brought the specific form under its influence, and bloodletting now operates in conformity with the law of adaptation (§ 137 c, 143 c, 847, &c.). Through the same law quinine may be peculiarly salutary in some cases where pleurisy is complicated with small-pox, if the former affection be owing to the remote causes which generate intermittent fever; but will exasperate the whole condition of disease if the pleuritic affection be owing to any other cause. Much, also, may depend upon a coexistence of different virtues in a remedial agent, especially in connection with the amount of its doses. Thus, quinia, in the dose of five or ten grains, may speedily arrest an intermittent fever by its febrifuge virtue. But that is bad practice; since, by its associate tonic virtue, it is likely to increase or to induce local congestions; thus leaving the patient imperfectly cured and subject to relapses (§ 769). But, in these cases, the local inflammation and venous congestion are so apt to be modified by the predisposing cause of the febrile affection, that repetitions of a small dose of quinine may be curative as to the whole condition of disease. I have twice seen, in my own family, the most formidable grade of remittent fever, of long duration and attended by the foregoing complications, ardent heat, thread-like pulse, loss of mind, &c., and where hope of recovery had been abandoned, yield to less than a grain of quinine, divided into sixteen doses (§ 137 d, 662 b, 756, 811, 813 b, 857). There had been repeated bloodlettings &c.*

870, b. This leads me to say, that the best experience sustains what is enforced by my interpretation of the modus operandi of remedial agents, that simplicity of treatment should distinguish the course of the practitioner. Where diseases are circumscribed, he will have little need of variety; while, on the other hand, the more compounded the affection the more likely will it be necessary to bring several agents into operation. In simple pleurisy an appropriate loss of blood may be the only requisite means, and an emetic at the invasion of croup. But if pleurisy be complicated with congestion of the liver, or with idiopathic fever, &c., several other agents may be necessary to meet these complications. Much, however, will depend upon

^{*} See Notes K L pp. 1119, 1120.

the stage of the disease when the treatment is begun. There must be harmony, however, among the virtues of the several agents, conforming to the general modifications of disease, and the existing sus-

ceptibilities to their influence (§ 150, 870 aa, 871, 888 b).

871. We have variously seen how the susceptibility of organs to the influence of remedial, as well as morbific, agents may be increased by antecedent impressions from other causes (143, 145, 149, 150, 556, &c.). This is fundamental in therapeutics, and carries us back to preceding statements (§ 672, 867, 868). The administration of remedies proceeds greatly upon this principle. One prepares the way for the favorable operation of another, or which last might be otherwise injurious. A remedy which is curative under one combination of circumstances may aggravate disease when that combination is a little varied. The cathartic which would not irritate intestinal inflammation immediately after bloodletting might greatly exasperate the disease if exhibited without the antecedent loss of blood. And so of vesicants, &c. Indeed, so profoundly and rapidly curative is bloodletting of inflammatory affections, and so greatly does it promote the useful effects of other remedies, or prevent their morbific action, that, whenever it is indicated, it should precede all others; and then it will be often found that it has taken the place of all others.

Hence a great doctrine in therapeutics, that the order in which remedial agents are applied should be in their best individual relations to the existing pathological state, whether that state may depend exclusively upon the primary causes, or as modified by the subsequent treatment (§ 137, d, &c.).

This principle, however manifest, enforces a thorough knowledge, not only of physiology and pathology, but of the exact capabilities of remedial agents, of their various doses, and of their modus operandi, in any given pathological state. Its highest practical attainment is the highest consummation of medical skill and science. It is the ne plus

ultra of medicine (§ 857).

872, a. The last section involves the principle which is concerned in the combination of medicines. By the union of two or more, and according to the exact virtues of each substance, and according, also, to the proportion of each, we create, as it were, a new remedy,-add a new one to the Materia Medica. It is thus seen that art may multiply remedial agents to an almost endless extent; and this explains the reason, in part, why the most enlightened practitioners do not often seek for desirable virtues in the inferior medicines. By variously combining two or more of a limited number new virtues are evolved, however analogous, in almost every prescription for disease.

By this process, what might be otherwise highly morbific may be rendered curative. The cathartic, which given alone might aggravate intestinal inflammation, may be often rendered safe and useful by the addition of a little opium or hyoscyamus; and thus, too, the necessity of antecedent bloodletting may be sometimes avoided. The narcotic so lessens irritability that the cathartic is innoxious, and is thus enabled to establish a favorable pathological change. How adverse to humoralism this single example, how confirmatory of the doctrine which I have taught of the action of remedies upon the properties of life (§ 188 a, 189, &c.)! Add to the cathartic, guarded by the narcotic, a grain, or more or less, of ipecacuanha, and new alterative Influences may spring up, of great power and extent; each ingredient, and according to the proportion of each, modifying, increasing, and extending the reflex nervous actions, but in such a combined manner that the compound acts as a whole, and not by its individual parts (§ $188\frac{1}{2}$ d, 224, 500 k-nn, 514 h, 889 k, $891\frac{1}{2}$ k, 896, 902).

Take another example; for these examples not only illustrate important principles, but are, in themselves, practically important. In a case of common remittent fever, near its invasion, we may proceed with decision, employ bloodletting, calomel and jalap, and speedily pretty well overcome the disease. The most that the patient will immediately afterward require will be rest, low diet, and mild influences by certain cathartics. The best of these, till the bile begins to assume a good yellow color, will be small doses of castor oil; for this cathartic exerts a peculiarly alterative influence upon the liver. When the dejections shall have put on a natural aspect, castor oil begins to irritate the intestine rather injuriously, and this effect increases as its repetition goes on; although given, perhaps, in the dose of a tea-spoonful, or a half tea-spoonful only, to an adult. It is also then apt to nauseate the stomach and prostrate the strength. Convalescence has now advanced too far for this active agent, and some other should be substituted to maintain a free secretion of bile, and to procure one evacuation, at least, daily. But I know of no mild cathartic which is exactly suited to this state of things. If we employ moderate doses of Rochelle salts, they operate too superficially; mainly upon the mucous tract of the intestine, and are also apt, in this condition, to irritate that membrane injuriously. Magnesia is liable to the same objection as it respects the superficial effect; and rhubarb alone is too stimulating to the whole system, and to the mucous tract. But it has the advantage of extending its influences to the liver, and of promoting the tone of the stomach and of the whole system, when this part of its tonic and stimulating effect can be properly restrained.

Now, the foregoing three agents in combination, and in proportions adapted to the state of the case, are exactly suited to the convalescent from fever who has passed the stage when castor oil ceases to be useful. The magnesia corrects the irritating effects of the Rochelle salts, and neutralizes any acid that may exist in the prime viæ, while each counteracts any injurious stimulant action of the rhubarb, so only the proportion of rhubarb be not too large. The rhubarb, also, in its turn, gives tone to the digestive organs, counteracts the prostrating effect of the saline substance, and imparts to the whole compound a reflex nervous action over the liver, by which a free secretion of bile is maintained till health is established.—See Note Ee p. 1133.

Nature has carried out this principle of combination very extensively, and has thus supplied, in numerous substances, a variety of virtues in each one, which are exactly adapted to the varying exigencies of disease. We see it strongly pronounced in the cathartic, tonic, and astringent properties of rhubarb; in the febrifuge and tonic virtues of cinchona; in the soporific, anodyne, and relatively astringent properties of opium; in the narcotic and laxative virtues of hyoscyamus, &c. Indeed, so manifold is this union of virtues, that art has availed itself of the opportunity, and elaborated many in the form of the alkaloids, &c., by which greater simplicity is obtained.

It is not unusual to meet with prescriptions in systematic, labor-

saving works, embracing several articles, with definite proportions of each, which are said to be adapted to certain forms of disease. This practice is not only wanting in philosophy, but is clearly empyrical; since the adaptation of remedies, both as to the ingredients of the compound, and their relative proportions, should be adjusted by the united circumstances of every case, as they may exist at the moment; especially in all the forms of acute disease. It is manifest, therefore, that this great object of medical science can be fulfilled only by a careful investigation of every case whenever a prescription is made. It implies a great range of inquiry, an accurate discrimination of the pathological conditions, and an intimate knowledge of the virtues of each remedial agent (§ 686, d). Hence, also, the voluminous reports of cases, with or without the "numerical method," are only useful for the institution of principles in medicine (§ 672, 867). It is so with every thing, with food itself in every case of disease. The principle extends even to light in the treatment of ophthalmia; which also supplies another proof of the coincidence in the philosophy that relates to the operation of light and other vital agents (\S 74, $188\frac{1}{2}$ d). And so with the agreeable emotions of the mind (§ 500, 539 c, 855, 1067).

If the reader will now attend, in connection with the foregoing principle, to what has been said of the nervous power (§ 222, &c.), of its laws of reflex action (§ 500, 512, &c.), and to other special circumstances which favor the operation of remedies (§ 143 c, &c., &c.), he will readily perceive the extent of his power in the judicious combination of a few only of the best remedies. But, to accomplish this art of combining remedies, in connection with the requirements in the preceding section (§ 871), demands an acquaintance with the whole ground which forms the basis of therapeutics.—Note Ee p. 1133.

872, b. And yet I would not abandon any part of the materia medica. I would hold it all, and all in connection; that what is good may be compared with what is indifferent or bad, and our knowledge of remedial virtues and remedial action be thus extended. There is also scarcely a recognized means of cure but is hallowed by the service it has done, and which it may do again, in enlightened hands, where the better means are wanting. It was with such intentions, and to promote the habit of a critical investigation of each member of the materia medica, that I was prompted to an attempt of arranging the whole according to their physiological aspects and therapeutical capabilities.

873, a. It is an important circumstance to be recollected, that many remedies are cumulative in their effects when employed in small doses; while the effects of others, on the contrary, lessen by use (§ 549-559). The action of the former, therefore, should be carefully observed during their progressive administration, that they may be promptly diminished or discontinued. The latter are not obnoxious to the equal objection of becoming morbific, as they must be often increased to obtain progressively their original effects; but much may be lost by neglecting the ascendency of habit in its aspect of diminished susceptibility (§ 535, &c., 841, 889 b).

These two important groups, however, are liable to some essential modifications. Mercurials, for example, in their constitutional alterative sense, are cumulative in respect to most adults, but very little so in regard to children, who are generally insusceptible of salivation

Again, in respect to agents which become inoperative from habit, this is often true of them only in certain small doses, and when frequently repeated. Tartarized antimony, in its minimum doses, generally diminishes the irritability of the stomach. But, if carried to the point of nausea, its effects will then be often cumulative, and the dose must be diminished, or incessant and aggravated vomiting may follow (§ 556, 841). Opium, hyoscyamus, &c., lose their effects, more or less, from habit, when continued at certain intervals, as twelve hours, and the dose, if expedient, may be increased; but if repeated as frequently, perhaps, as once in six hours, or less, they are cumulative, and the dose must often be diminished. By-and-by, however, under this frequency of exhibition, irritability becomes obtuse in relation to the agent employed, the opposite influence of habit obtains, and the dose must be increased to procure the original effect.

Many agents continue to produce about the same effects in the same doses, administered at certain intervals, however long continued. Such is true of ipecacuanha, and those vegetable substances which are allied to it. So, generally, of iodine, and many of its combinations. Much, however, depends upon the intervals between the doses. Unlike tartarized antimony, which it resembles in so many respects, ipecacuanha is cumulative as the intervals shorten below four hours, when the dose is a grain. The ipecacuanha will then often produce nausea and vomiting, while the antimonial, though repeated at far shorter intervals, is apt to lose its effect unless progressively increased

to an extent which would prove emetic at the first dose.

873, b. In larger doses, or in their greatest admissible extent, all the foregoing agents are apt to be cumulative. This is true of the frequent exhibition of cathartics and emetics, though more so of some than of others. The dose of aloes which purges from the beginning must be often greatly lessened at the subsequent doses; or what was originally only a mild effect may soon become a violent one. This is also remarkably true of castor oil. All the cathartics, also, when administered daily in small doses, commonly raise the irritability of the intestine, and operate with increasing energy, though in some of the cases a part of the result may be due to an increased production of bile (\S 516 d, no. 6, 556 b, 841, 889 m, mm, 902–904, 1057 l).

874. It is an important circumstance, philosophical and practical, that the operation of narcotics is remarkably influenced by pain, and by certain states of the great centre of sympathies, as in *delirium a potu*. It is fatally opposed to the physical hypotheses, and to therapeutical conclusions from experiments on animals or on man in a state

of health.

It is also interesting to the medical philosopher that pain has no remarkable modifying influence upon any remedial agents excepting the narcotics; and of those, such only as have a special relation to

sensibility (§ 194, &c., 891).

875. We have now seen, in a general manner, that the susceptibility of the vital properties to salutary impressions, and their inherent tendency to a state of restoration when driven by disease from their natural standard, has given rise to two general modes of treatment, which are familiarly known as the active and the watching or expectant (§ 853).

876. The active method consists in the application of such remedies

as produce artificial impressions. It comprises all that is attempted by art, in a direct manner, to promote the natural curative process. By this method, therefore, we forcibly institute those new pathological conditions which are most conducive to a return of the natural physiological states (§ 150, 854 b, 855, 856, 901, &c.).

877. The system of watching, or the expectant plan, leaves Nature mostly to herself; only keeping obstacles out of her way. In its greatest latitude its advantages are exemplified in the self-limited diseases; but there is a period in all dieases, terminating favorably, when art should surrender the case to Nature (§ 858, 861, 867, 868 a).

878. So many evils have resulted from abuses of the active method, that great numbers, not considering that Nature is embarrassed in these cases by ignorance or carelessness, and, withal, having erroneous views in physiology themselves, do little else than watch. This is remarkably true of the homeopath, whose lessons from Nature have taught physicians that all the virtue does not lie in the amount of doses, and that a foe has arisen who can be exterminated only by consulting the philosophy of disease, and the modus operandi of remedies.

Nevertheless, although medical philosophy and a knowledge of the mode in which remedies operate be indispensable to the right treatment of disease, the community look only at the results; and while the homeopath cultivates his mind, there will be no inquiries, no interest, as to his theories. In America these innovations cannot prevail extensively, since the contrast will be vastly on the side of our Hippocratic practice (§ 709). But, in every section of the country there are some who are prone to a large and indiscriminate medication; and while this evil exists, homeopathy, in its original practical sense, will make its more successful demonstrations. Nor can it be doubtful that the tonic and stimulant practice which has risen in our cities, and which still sways the British profession (§ 621, a), would yield a harvest to those who suffer Nature to take an unmolested, however unaided way.*

It is due, however, to truth (fiat justitia ruat cælum), that the physiologist concede to the homœopath that his hypothetical views may be directed by an enlightened understanding of the properties and laws of healthy beings. Upon that ground, indeed, his hopes can alone repose; and even his doctrines in pathology and therapeutics are a thousand-fold better, more rational, more consistent, more conducive to health and to life, than any or all the tenets of the chemical and physical schools. With the one there may be a great deal of misapplied philosophy; with the other there is certainly none at all (§ 892, i).

879. It appears, therefore, that the active and expectant modes of treatment should be more or less associated; either taking the lead according to the general character of the disease, and the particular circumstances of individual cases. Having made the requisite impression by the active method, we should watch till another remedial change may be advantageously produced. When all is steadily in the right way, we should do nothing but watch. Another impression by an active agent would disturb the restorative process, and might so derange the vital states as to establish a condition of disease which art and nature together might not be able to surmount (§ 137 d, 150, 151, 854).

^{*} See Dr. Forbes's "Young Physic.;" also, Prof. Lawson's, and Medico Chirurgical's Reviews of the same, 1846.

880. Having, I say, placed the morbid conditions in the right way for their subsidence into health, but little else remains than to withdraw, in good time, the active interference of art. Much, however, as I have said, may remain to be accomplished by what may be called restorative means; such as a well-regulated diet, exercise, exposure to the air, &c. (§ 855). In protracted diseases Nature may also require the aid of tonics and stimulants; and this is mainly the advantage which they bestow. They are rather, therefore, adjuncts to medicines that are curative, than positively curative themselves. The same is also true of those narcotics which address themselves to exalted sensibility or irritability.—See Note Ee p. 1133. Also Note F.

881. Though by the system of watching we intrust Nature with the cure, the active interference of art may be demanded by supervening obstacles. Such is the case, as we have seen, when visceral inflammations spring up in the self-limited diseases (§ 858). In these affections, also, in their simple states, general arterial excitement may become so excessive as to require the loss of blood, or alterative doses of tartarized antimony, &c. The remedies are designed for these specific objects, and not with any expectation of arresting diseases which have a strictly natural course and termination. The same principle is applicable to all other forms of disease; according to the na ture of the contingencies that may arise after the restorative process shall have been introduced. It is alike employing constitutional laws

882. It is no uncommon prejudice that certain local, and even constitutional forms of disease should be allowed to continue for the prevention of some apprehended greater evil. This practice is founded upon the humoral hypothesis, and is one of the strong exemplifications of the fallacy of that doctrine. The intermittent fever is thus allowed to persist, that some peccant matter may be concocted and expelled; ulcers are cherished as outlets to vicious humors, &c. But, we are never benefited by the continuance of natural diseases. The sooner we get rid of them, the more shall we insure the chances of prolonged life, enjoy an exemption from corporeal and mental suffering, and manifest our common sense.

883, a. In considering what is to be done in the treatment of disease, we speak of the Indications. These consist of the suggestions that may be afforded by all that relates to the state of the patient. They refer to the symptoms, the seat of the disease, its remote and pathological causes, its duration, the habits, occupation, temperament, constitution, age, and sex (§ 686, b).

883, b. And here we may go back to the origin of our Science for one of those summary statements which can flow only from an enlightened and comprehensive view of organic philosophy, and which

no subsequent observation has improved.

"Consider well," says Hippocrates, "the nature of causes, the nature and seat of the disease, what is most suitable to-day, and what to-morrow, what the vigor and what the mildness of treatment. neglect of either may be fatal to the sick. Reason as a practitioner, and practice with reason." "Again, an important thing to be done is to consider the seasons of the year, the various changes, and the differences of their effects. Next, the winds, particularly such as are common to all nations, and such as are peculiar to certain countries." "The knowledge of disease is to be obtained from the common nature of all things, and from the nature of every individual; from the disease, the patient, the things that are administered, and the person that administers them, for the case becomes easier or more difficult accordingly. We are, also, to consider the whole season in general, and the particular state of the weather, and of every country; the customs, the diet, the employment, the age, of every one, the conversations, the manners, the taciturnity, the imaginings, the sleep, the watchings, and the dreams; and how far vellications, itchings, and tears, are concerned; and what the paroxysms are; what the evacuations by stool, or spitting, or vomiting may be; and what changes may happen from one disease to another, and their various consequences. Sweat, cold, shivering, cough, sneezings, sighing, breathing, belchings, flatus (secret and audible), hemorrhages, and hemorrhoids, are also to be considered, together with the consequences of each" (§ $5\frac{1}{2}$ a, $350\frac{2}{3}$, 821 c-823).—Note Oo p. 1141.

884. When the foregoing indications are subjects of attention we pursue the *rational* system, which is so called in contradistinction to

the empirical.

The rational treatment looks, also, at the physiological states of the body, and considers disease in its relations to those states. It is constantly concerned about the laws of vital actions, and regards disease as consisting in their modifications. In short, it proceeds upon the broad ground of inductive philosophy, and, therefore, takes in its

scope all the principles of medicine (§ 639, a).

The empirical practice, on the contrary, discards every thing but a few prominent symptoms, and would as soon relieve the pain of pleurisy by opium as that which attends a spasm of the stomach. Such, rather, is the common acceptation of empiricism. But, it is more a prevailing usage with the ignorant, and with those who discard the rational treatment, to be regardless even of abstract symptoms, and to be mostly swayed by the humoral hypotheses (§ 4 b, 744, 821, 824, 830, 835).

885. Symptoms, however, are the most essential, in their relative bearing, in the series of indications. They inform us of the organs affected, conduct us to a knowledge of the pathological cause, and frequently contribute their aid in detecting the nature of the remote causes, by which the pathological is determined (§ 644, 667, 678).

A few diseases have a particular symptom which is pathognomonic; as the eruption in small-pox, measles, &c. But signs of this nature are very rare, and still rarer the strictly vital phenomena (\S 682, b).

In the great class of inflammations there are certain symptoms common to the whole, which, being more or less present, denote the presence of this disease, and thus become a general guide to the treatment through the light which they shed upon the general pathology. That treatment is the antiphlogistic; but whether it shall consist of bloodletting, cathartics, alteratives, blisters, &c., individually or collectively, and to what extent, will depend not only upon the amount and severity of the general symptoms, but often, also, upon many others less uniform that may relate to each individual case, and which frequently mark some special modification of the common form of inflammation (§ 721, 722).

886. Next in importance to the immediate symptoms, and as often indispensable to a correct apprehension of the pathological cause, is

a knowledge of the predisposing causes. This, also, has been amply shown in its appropriate places (§ 644, 742, 776, 813, &c.). To these causes, besides the more immediate, belong the innate tendencies to particular forms of disease, and, more or less, all the natural and acquired temperaments, and all the habitual deviations from the natural standard of a sound constitution (§ 143-147, 561, 661, &c.). It is evident, therefore, where there are many remote causes concerned in the production of any given case of disease, that a few only, perhaps but one, have an important agency. Those few, or this one, are most important to be known; and so of the others in proportion to their modifying influence. In the great families of fever and inflammation there is generally but one principal cause for each modification, which is generally transient, or may appertain to the constitution. In the latter case, as where phthisis pulmonalis arises from the combined influences of cold, moisture, errors in food, &c., I regard these apparently predisposing causes as simply exciting, and assume the natural predisposition as the predisposing cause (§ 661).

887. The great value, then, of a knowledge of symptoms and of the remote causes of disease is that of conducting us to a right understanding of the pathological cause. In forming our indications of treatment from the symptoms alone we may effect the removal of many, but in so doing we may aggravate the disease, and perhaps destroy the patient. This is conspicuously seen in the bark and wine treatment of those congestive fevers which destroy so many of the human family; one symptom only being the guide of practice in such cases. "Debility," indeed, is practically rendered the disease itself by philosophers of the tonic and stimulant school (§ 476 c, 487 h, 488½,

569, 621 a), though it be a mere failure of voluntary power.

388, a. It is commonly a simple problem for the enlightened and observing practitioner to resolve the general character of any pathological condition. With this knowledge we are ready to act in a certain general manner, or, as it is called, upon general principles. But, there is something far more difficult, though often scarcely less important to be known, in many cases of disease; namely, the particular species, or rather variety, of inflammation, of fever, &c., which any given case may present. Having found this last important point in the cases supposed, and settled the modifying influences of contingent causes, we are fully prepared for all the details of treatment.

888, b. Owing to variations in the pathological state of many cases of a common form of disease, but where no fundamental change in the general character of the affection has happened, it may be necessary to employ remedies in apparent opposition to each other. But, in these cases, there is no violation of principle, no inconsistency of Nature. A different conclusion only proves that we do not interpret Nature correctly. To reconcile the seeming inconsistency it is only necessary to recollect the explanation which I have given, that our remedies cure by instituting new pathological states, and that a certain variation of disease from that condition to which loss of blood is generally most appropriate may render stimulants, along with antiphlogistics, the best means for instituting the pathological change that shall be most conducive to the restorative process (§ 752-756, 870-872).

888, c. There are a few fundamental points to be carefully consid-

ered in all cases in relation to the effects of remedies. They refer to the principles and details already propounded.

1. The direct local effect of remedies upon the part to which they

may be applied.

2. Their effects upon remote parts through reflex nervous action.

3. Their ultimate effects after their direct action is over.

4. The general influence each remedy may exert upon the course and termination of disease.

888, d. It is one of the most remarkable facts connected with constitutional principles, that those organs which are most important to life are either within the direct reach of medicine, or they sympathize with such more powerfully and more readily than do the less important (§ 129, &c.)

It is also to be observed that the parts through which we operate artificially, and with which those vast and important sympathetic relations subsist, are of an external nature, and admit the application of

powerful remedies to their surfaces.

And yet, again, observe that whenever no useful results would follow the direct application of remedies to other organs, such organs will not admit their application without injury to themselves and to others remotely situated. Nature has therefore kindly given to us two surfaces through which we may act upon all diseases; while she has placed a barrier against the entrance of all morbific agents into those parts where the direct action of remedies would be useless or detrimental (§ 278 and references there).

888, c. I now leave the subject of therapeutics in its general aspects, to illustrate the doctrines which I have propounded, and to advance the rational treatment of disease, by investigating still farther the modus operandi of remedial agents, and as that philosophy is modified in its connection with the operation of loss of blood. At a future time it will be my purpose to carry the same philosophy through all

the details of the Materia Medica.

Before proceeding, however, to the summary consideration of the modus operandi of remedies, I shall make a more practical analysis of the therapeutical effects of certain agents which are capable of a wide range of influences, but between which the resemblances are so obscure as to have contributed not a little to the errors which prevail in respect to the impressions they produce, or discourage others from all expectation of ever attaining any knowledge of their operation beyond their direct manifestations. I shall select such agents for this purpose as will be most conducive to a ready apprehension of the modus operandi of all others, especially the most important and most neglected of all—neglected practically as well as philosophically—loss of blood. Those agents may consist of cathartics, astringents, tonics, narcotics, antispasmodics, arsenic, Peruvian bark, or, rather, the alkaloid quinia, iodine, and ergot. The last four will illustrate what is known as specific action. In the Peruvian bark I shall also bring into view an agent possessing two prominent and rather opposite virtues, and thus attempt the just application of a compound agent to important problems in disease. So, also, with rhubarb, &c., when speaking of astringents.

While considering the therapeutical uses of the foregoing agents, I shall also indicate their morbific capabilities; and, as an important

means of engaging attention, I shall dwell upon their abuses.

The advantages of irritants, applied externally, especially vesicants, will follow in the train; and bloodletting, the first in importance, will be reserved for the last, that it may have the united testimony in its behalf of all that precedes.

I am also prompted to these inquiries by a desire to introduce the treatment of inflammation, fever, and venous congestion, along with

my investigation of their pathology, &c.

CATHARTICS.

889, a. What I may now say of cathartics is a continuation of what has been set forth in section 863, d. Their definition as founded upon their most sensible and uniform effect is—agents which increase intestinal evacuations. But this acceptation scarcely refers to any of their important physiological and therapeutical influences; which are just as intelligible, through the various resulting phenomena, and the laws of reflected nervous actions, as the evacuations they produce.

The increase of peristaltic motion, and the augmented product of the intestinal mucous tissue, spring from the irritation which is exerted upon that tissue by the action of cathartics; and the whole group of these agents are more or less capable of producing those results. It is through this irritation, which is variable in its kind according to the nature of the cathartic, that all the remote influences which they exert arise; and as these remote effects depend upon modifications of the nervous power corresponding with the nature of the primary impression, it is obvious that one cathartic may be speedily curative, while others may be profoundly morbific, in certain given conditions of dis-

ease (§ 52, 150, 227, 228, 500, $638\frac{1}{2}$, 1088 d).

But cathartics exert, also, important effects upon remote organs by continuous sympathy;* as upon the stomach, and especially upon the liver (§ 498). It is extremely common, for instance, when a cathartic is about operating, for nausea or vomiting to take place; which, however, may result from remote as well as from continuous sympathy. And here I bring the analogous influences of leeching into connection with the illustration to which I formerly adverted (§ 498, f, g). the foregoing manifest irritation of the stomach we see, also, how the vital condition of that organ may be at the same time profoundly affected, either for better or for worse, by the mere action of cathartics upon the intestine. And that this is truly so is evident from the manner in which we often see gastric disease subside, or produced, or increased, immediately after the nauseating effect of a cathartic. But, should the same results happen without nausea, we know from the connection of phenomena now stated, that they have proceeded in the more obscure instance from exactly the same influence, though the prominent symptom of nausea happen to be absent. We thus arrive at the farther knowledge not only that catharties throw their powerful influence, by reflex nervous action upon distant organs, in virtue of their intestinal action, and in the same manner as the stomach is affected by the remote process, but how, also, this organ is simultaneously rendered the point of departure of other profound influences upon distant organs; -their main effects depending on reflex nervous actions.

If we now look at what is going forward in the liver, at the same time, we shall see that here, also, are phenomena which denote the same principles, and the same chain of causation. Take, in the first

^{*} Continuous influence of these Institutes (§ 129 c, f, 498 a).

place, what is most obvious to the senses, the bile; and we find it often greatly increased during the operation of cathartics. Now it would be clearly wrong to explain this phenomenon upon any other principle than that which I have assigned for the nausea and vomiting; that is to say, by remote and continuous sympathy,* just as muco-intestinal inflammation is extended by reflex and continuous sympathy into the ducts of the liver (see § 829). Here, also, as in the case of the stomach, we find that disease simultaneously subsides, or is produced, in the liver, and we know that it depends upon the same causes that had given rise to the production of bile. But this is not all. liver, from its important connections with other parts, now occasions, as in the case of the stomach, reflex nervous influences upon distant parts, while, moreover, it may yield important relief to the brain, or the stomach, or intestine, &c., through an increased secretion of bile (§ 863). The irritation of the intestinal mucous tissue which determines the nervous action upon the muscular coat (§ 514 f) is the occasion of extensive alterative reflex actions upon other structures, and the former phenomenon is a key to the latter, and of the modifications which result in increased secretions, the abatement or increase of disease, etc. Organic actions alone manifest change under such influences, never the muscular, and hence the difficulty of reasoning from the latter to the former ($\S 893\frac{1}{6}$).

889, b. But, cathartics often produce their full curative effects upon remote organs without determining any alvine evacuation; and this proves to us that the great curative operation of cathartics is of a physiological nature. Nothing, indeed, is more common than to exhibit cathartics when the intestine is empty; and all the good we then obtain from them (and it is often great) arises from those vital influences of which I have been speaking. If much bile, mucus, &c., happen to be discharged in these cases, they are mainly generated during the action of the cathartic ($\S 694\frac{1}{2}$). In almost every acute disease of much importance cathartics are administered, and if not with the intention of which I am speaking, they are employed empyrically. When no such specific object is contemplated, they are given merely because it is customary to do so; always excepting the humoral

interpretation (§ 456 a, $461\frac{1}{2}$, 473 c, 478 b, 483 c, 1058 d).

SS9, c. In my Arrangement of the Materia Medica, I have placed the chloride of mercury and blue pill as the first in importance among cathartics; and yet their purgative effect is comparatively very little with many of those which I have arranged as the most inferior. This was plainly done for the reason that the curative influences of these mercurial preparations are far greater, in a general sense, than those of any other cathartic. Experience assures us that the arrangement is right; while philosophy, as also founded on observation, enforces the truth that the most drastic cathartics inflict their injuries through exactly the same principles that the less purgative exert their good effects, differing only in the irritations and reflex nervous actions.

We thus see how liable definitions are to lead us astray; and this is true of most of the designations which I have retained in my Physiological Arrangement, and more particularly so of those general denominations, such as demulcents, revulsives, deobstruents, &c., which

I have excluded (§ 729 b, 819 a).

889, d. We may make up our minds, therefore, that the mere purgative effect, or the evacuation of the fecal matter, abstractedly con-

^{*} The case is the same here as when stimulants or mechanical irritants applied to the conjunctiva instantly excite the lachrymal gland to the production of tears.

sidered, is one of the least that is exerted by cathartics; and nothing can be said in behalf of their supposed action upon the blood.

889, c. Nevertheless, it should be steadily considered that fecal accumulations are a source of mechanical irritation, at least; or, if they consist more or less of fermented food they also irritate in virtue of their specific properties, and, in both the cases, exasperate remote diseases through the same physiological laws that are relative to the good or bad effects of cathartics. It is then an object to remove these exciting causes. But, if none of the important vital influences of cathartics be then contemplated, we should employ such only as are mild, and whose action does not extend much beyond the intestinal canal. Precisely the same rule should also obtain in the administration of emetics. Tartarized antimony and ipecacuanha are all we want for profound curative virtues; and sulphate of zinc for superficial action, or, at most, associated with one of the others where gastric irritability is rendered obtuse by narcotic poisons.

889, f. Does the reader now inquire why it so frequently happens that the best effects of cathartics, in diseases remote from the intestines, are obtained only when they operate decisively, and perhaps powerfully? The answer is important; for it goes far to illustrate the modus operandi not only of cathartics, but of all remedial agents. It is, then, because this strong impression upon the vital condition of the intestinal mucous tissue is necessary to establish those reflex nerv ous actions on remote parts that may be the seat of disease which result in such a change as brings about their own natural curative tendency. The repeated evacuations are a necessary consequence of that requisite impression upon the intestinal mucous tissue, and serve as an evidence that such necessary impression has been produced.*

889, g. It appears, therefore, that the results which follow the action of cathartics may affect powerfully all organs, however remote they may be from the intestine, without resorting to the common assumption of absorption, or to any doctrine in the humoral pathology. In all this, too, we are aided not only by our knowledge of the physiological relations of the intestinal mucous tissue to all other parts through the sympathetic nerve, but by its anatomical connections with the liver and skin, and by its vast extent. It is also the seat of some of the most important vital functions, and it is here that the whole lacteal system takes its rise, and here is the great concentration of the sympathetic nerve in the semi-lunar ganglion and solar plexus, with the contributions from the pneumogastric nerve and spinal cord.

It is owing to these vast and important anatomical and physiological connections, that, when disease springs up in the intestinal mucous membrane, it sheds its morbific influence abroad over the whole system; now developing, by reflex actions, cerebral inflammation or congestion; now of the liver; again, inflammation of the skin; at another time, of the bladder; in this subject rheumatism; in that, scrofula; in another, croup; in others, inflammation of the fauces; here, of the eyes; there, of the nose; here, an attack of the gout; there, abortion; and so on, through every part of the organization.

Considering, therefore, I say, the foregoing anatomical and physiological characteristics of the mucous tissue of the alimentary canal, and how diseases of this membrane may give rise to disease in every other part, we may readily comprehend how it is that cathartics exert

^{*} See Note G p. 1116.

powerful sympathetic effects upon distant organs when rendered unusually susceptible by disease. And so of all other remedial agents, internally applied, according to the nature of their virtues, their doses, &c. The philosophy lies mostly in reflex nervous actions.

889, h. From all which it follows, that three principal advantages

are contemplated from the operation of cathartics; namely,

1st. Their sympathetic influences, remote and continuous.

2d. The increased secretions to which they give rise; especially from the intestinal mucous tissue, and from the liver.

3d. The evacuation of the fecal matter, which, in a general sense,

is the least of all.

889, i. Certain cathartics affect certain portions of the intestinal mucous tissue more than other portions; and this is owing to the peculiar modifications of the organic properties in different parts of that tissue, and the peculiar vital relations of particular cathartics to one or another of those different parts (§ 134-137, 150.) These special relationships should become the subjects of critical investigation, since it often happens that cathartics may be advantageously selected with a view to these exact physiological conditions. The fact is more or less understood, but not so the philosophy. There are some great errors, however, as to the facts. Aloes, for example, is supposed, universally, to exert its effect especially upon the large intestine, while, in truth, its influence is vastly more upon the jejunum and ilium, as abundantly manifested in irritable states of the small intestine, and by the manner in which it aggravates the general arterial excitement of The irritation of the highly-sensitive anus fever and inflammation. which has given rise to the prejudice depends mostly upon the sudden production of morbid bile which aloes elicits by its special influence upon the liver; and this, also, is a proof of its direct and main effect upon the superior portion of the alimentary canal (§ 718). But again, we have an opposite demonstration of the same philosophy in the failure of aloes to be attended by this irritation of the anus in the absence of hepatic derangements; and then, also, there is comparatively little bile evacuated ($\delta 1063 \ b$).

The great governing principle, however, in the selection of cathartics, should be their known effect upon disease, according to its seat and pathology. If applied with a view to their special action upon one part or another of the intestinal canal, they will be often liable to the worst practical consequences unless the philosophy which I have set forth upon this subject be considered accurately along with experimental observation of the relative virtues of the different cathartics; and, I may add, that the more these relations are studied, the more apparent will that philosophy become in its truth and importance (§ 52, 134–137, 150, 1058 b, and references there, 1063 b, 1065 b).

889, k. From what has been hitherto said of the philosophy of life, and as modified by disease, we readily understand how cathartics may be greatly varied in their action by associating two or more together, or by uniting with them agents from other groups. Each combination is a new remedy, and a new one, too, according to the exact proportions of each ingredient. How important, therefore, a critical regard to all the details involved in these suggestions! But, there is no problem, I say again, more difficult in practical medicine; and next to that is the right dose of the whole, or of any single agent, and

next in order the time for its repetition, or for the substitution of some other remedy. Such combinations act as a whole, and not only upon the intestinal mucous tissue according to their collective virtues, but develop and reflect upon other parts an alterative nervous influence in a corresponding manner. Thus the nervous influence is on common ground with those agents as an exciting and modifying cause, since the latter increase and modify the mucous product by their direct action, while the increase of bile, urine, sweat, &c., depends upon reflected nervous action as the exciting cause (§ 222–233 ½, 461, 512, 647 ½).

If we now take an example, familiar as it may be in practice, it may help our philosophy as to all other combinations of remedies, and guide the practical hand in regulating the proportion of ingredients, the doses, &c. Thus, cathartics may become completely inoperative, as such, by the addition of opium. This is done by rendering the irritability of the intestinal mucous tissue so obtuse that it cannot be roused by the irritating virtue of the cathartic. Diminish the proportion of opium, and the cathartic irritates moderately and purges slightly. Reduce the narcatic still more, and the cathartic irritates more and purges more. Omit the opium, and the purgative effect may be violent and attended by great pain. And, in doing all this, we also variously modify the reflected nervous influences of all the agents which are thus employed (§ 227, 228, 500, &c., 872 a).*

This is an example for all other combinations of remedies; for the same philosophy is concerned throughout. We see, too, in this example, how the combination acts as a whole. The cathartic and narcotic simultaneously impress irritability and sensibility; each exerting its force upon those properties of life in the ratio of their proportions, and according, also, to the existing state of the properties (§ 137 d, 150, 189, 191, 872 a), and so will be the modified reflex nervous actions.
